You can never be sure that someone hasn't swapped your
antenna for equivalent circuit components but the
MFJ-259B antenna analyzer works for me.

I would do a frequency sweep with an MFJ-259 or similar to cover the
frequencies of interest. A noise bridge and a receiver would be another
approach.

A few specifics would aid in pointing you in the right direction.

"Seems to be the white house monitary opolicy too (I wonder if they know we use the dollar?)."

The white house is dense. The U.S. has been spending 8 billion a year just to improve Iraqi infrastructure so foreigners might invest in a place with no law and order. The infrastructure is in desparate need of repair from war, sabotage, crime, and neglect.

Bush needs to put aside his bias against socialist programs, in a state which was socialist under addam, and inaugurate WPA and PWA type programs tp put Iraqi idle minds and hands to work now. This would immediately put money into the hands of spenders. It would give Iraquis a stake in the future of Iraq.

Halliburton, Kellog, Brown and Root, et al can`t do it. They aren`t Iraqis. We`ve been unable to enforce law and order and won`t until it is clear to be in the best interest of Iraqis to maintain law and order.

Best regards, Richard Harrison, KB5WZI

Hi Richard,

As acknowledge by the white house, this Trillion dollar sink hole is putting money down the toilet by buying bullets to protect against suicide bombers (hasn't worked - ever - this has been going on since Nobel invented dynamite).

Simple resolution with that same Trillion dollars that WOULD solve things would be to set up shop next door to the guys strapping sticks of TNT to the Iraqi's vests. Instead, offer to strap packs of $100 for every stick of dynamite they might have lined up for.

Let's say that they would come out looking like a Chia Pet with $50,000 glommed onto them.

We could do this with every man, woman, and child in all of Iraq.

It won't happen, of course, because there is no will to win the war - only to fight one. Except for those who have something better to do with their lives (indirect quote of the draft dodger who shunned military service to run this corporate franchise called the Pentagon).

If you have an antenna present the receiver noise level should
increase when you connect the coax. If there is no antenna there
should be no or much less increase in the noise level. This assumes
you are using good low leakage coax.

Asimov wrote:
"There is a thing called metal fatigue of which I was strongly reminded this spring."

Yes. It usually begins with a microscopic crack. The greater the stress, the shorter the life. Damage is cumulative. It is affected by temperature and surface finish.

Some metals such as steel and titanium have lower stress limits below which they are mostlly im,mune to failure from repeated flexing. Other metals such as aluminum and its alloys have no such immunity and eventually fail under repeated flexing. In these, designs are kept below the fatigue threshold for the number of stress cycles expected within their lives. Or, a lifetime is specified and replacement is required. Another technique is non-destructive testing to find cracks and the piece is retired for cause.

Exactly

I also have a W6RCA type antenna up...80m dipole in the trees 25-50 feet, fed by 98 feet of homemade 4" spaced ladder line, and ending outside the shack wall with a way to add-in lengths of the feed line by 1 foot, 2 foot, 4 feet or 8 feet. This allows tuning the feedline onto any ham band almost via harmonic relationship of the bands . You endup with a multiple halfwave feedline and whatever swr the antenna runs shows up at the feedpoint (50 ferrite coax to ladder balun 1:1). Best antenna I have. Always better to tune the feedline, and translate the antenna characteristic from the remote locale to the shack wall. There is some loss I guess, but I cant detect it or measure it, and I dont care because the antenna radiates and receives and I get 59 reports.

Either use a TDR, or something that measures RF impedance - an SWR meter, an impedance bridge, an antenna analyzer, or even a signal generator and a scope. Sure there's a path for current flow, but only for sure at RF, so that's where you have to detect it.

Or, modify the antenna very slightly - put an RF choke or a
large-value resistor across its feedpoint. This will give you
something to probe for at DC, without affecting the antenna's
performance at RF.

When WW-2 ended, Churchill was out.

You need something like a battle to be a wartime leader. Hitler had "Mein Kampf". He and Mussolini wore military uniforms. So did Tojo and Stalin (Saddam`s role model). Military costumes are worn by most Latin-American dictators. Fidel Castro (El Comandante) is an example. Take Mexico, their revolution was almost a century ago, yet the party which ruled the country until the last election was the Partido Revolutionario Institutional. Got to keep that military thing alive to be the leader of choice. Fortunately our president is required to be a civilian.

The war may get you re-eleected no matter how bably you wage it.

Best regards, Richard Harrison, KB5WZI

> I have diverged. I do not think you can do that.

Physics doesn't have a book of code violations, Cecil. It's more like a big set of equations. The rules are mathematical. I've already shown you where you made mistakes. What tortuous obligation have I encumbered that dooms me to an eternity of repeating these things to you? Just try turning down the squelch a little.

>decent SWR on 440 & seems to work fine.

They'll usually work as-is on 440, but aren't entirely efficient. SWR is higher, and so is the radiation angle - a good deal of power ends up warming the nearby treetops and hilltops rather than going out towards the horizon.

I've seen at least three ways suggested to construct a more-effective dualband J-pole:

[1] Separate matching arm and feedline for 440 (the "copper cactus" design)

[2] Adding a downwards-pointing, shorted-at-the-top quarter-wavelength stub (coaxial or arm) partway up the radiator, leaving the distance between the open end of the stub and the top of the main matching arm equal to 1/2 wavelength at 440. The stub presents a high impedance to the 440 power, constraining its current to remain mostly in the 1/20-wavelength-at-440 part of the radiator.

Edison Fong WB6IQN published a design in QST (February 2003), which uses this approach to create an improved 2-meter/440 twinlead J-pole design. The same trick ought to work with a copper pipe J-pole, I imagine. [There are some publishing errors in the QST version of Ed's paper... he's got a corrected version available, I believe.]

[3] Add a 1/2-wavelength 440 parasitic radiator, mounted next to the bottom of the 2-meter radiator on standoffs.

This one is a bit speculative. There's a published design on the ARRL website which uses this approach to improve the radiation angle for a center-fed vertical 2-meter/440 dipole, and I think the same trick ought to work for a copper-pipe J-pole if you put the parasitic radiator on the opposite side of the antenna from the matching arm.

2764. Re: Feed point chokes for J-poles: how close?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-14 23:41:33 UTC
From: Crazy George <munsch@atglobal.net>
Message-ID: <42d6fd33_1@news1.prserv.net>
Source record: 73329

The purpose of the choke(s) is to reduce/eliminate coupling between the antenna and feedline, thus suppressing feedline
radiation. Running the coax inside the element effectively does this for the upper elements, so the bottom one is the
only one of concern. However, since it will couple to all the feedlines, they all need to be choked, but only for the
frequency of the lowest element. One simple way to do this is an isolated metal tube a quarter wave long just below the
mounting stub.

No. The elevation angle of the first (or any) lobe is formed by the sum
of the main and the ground-reflected signals. If you tilt the antenna you
stop illuminating the two rays equally.

Message-ID: <11de0vt4muq7505@corp.supernews.com>
Source record: 73335

No, except maybe mechanically. The pattern of the antenna itself is quite broad in the vertical plane. That is, its elevation pattern is pretty fat unless it's a very long array, so tilting it in elevation doesn't make much difference. The overall elevation pattern, except at pretty high angles, is dictated by the ground reflection, which is primarily determined by the height of the antenna above the ground.

If you're working satellites or otherwise line-of-sight where no significant amount of ground-reflected signal hits the ground, then yes, you want to point the antenna at the target. But again, unless the Yagi is a very long one, its elevation pattern will be broad and you can be pretty sloppy about the elevation angle.

A few minutes spent with a modeling program will illustrate these effects clearly.

2771. How to get RG-213/U from shack to exterior

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-15 02:52:06 UTC
From: John N9JG <john@gotwals.xremovey.com>
Message-ID: <db78ckuvf1@mailhub227.itcs.purdue.edu>
Source record: 73336

My shack is on the second floor, and I will be feeding a vertical with RG-213/U. In addition to the antenna feed line, I will also need to run a wire from the shack to a ground rod. The room housing the shack has one window, which is just to the left of the equipment table, and the window is an aluminum single-hung type. The house wall has aluminum siding on the exterior.

My current plan is to drill two holes, one for the coax and one for the ground wire, in the wood frame that is just below the bottom of the window. I expect to sell this house in the next year or two, so I want to be able to easily patch over any holes I have made in the wall.

Any advice and information will be gratefully received.

The CCD is one of those arm-chair designs that is a gift to mankind in
the form of gain from a dipole.

To being with, the theory behind it is that this antenna is frequency
specific, and that it is much larger than the standard dipole it
replaces. If this is news to you, then there's trouble ahead.

Continuing, the theory behind it maintains that each section is tuned
and presents a current maxima that aids with each of its neighbors to
thus increase gain. The standard current distribution along the
standard dipole is cosine shaped by and large. For the CCD it is
presumably linear - until you get to the ends of course where it
plummets to 0 in the last section. Myself, I respond to this
description of an antenna by parts as being much like a fresnel lens
in its conception.

However, modeling, such as I have done, fails to substantiate the
claims even if through contortions and exasperation I do manage to
attains some semblance of the linear current model.

Further, physical models bear out no particular boon to mankind that
has been extolled.

>dont think Ill be reading this group everyday...who cares
>about the british pound? EH?

This falls into the category of off topic response, something you presumably eschew and simultaneously indulge in. This, too, is a commonplace activity.

I am happy to respond to all topics that interest me. There are other endlessly boring discussion of antennas - notably those that have survived hurricanes as evidenced by photo doctoring - that remain on topic, and off interest. I don't complain about it though, except to recite as a parable.

Hi John,

Open the window 3".

Get a piece of wood as wide as the window, and that same 3" tall.

Insert the drilled piece of wood into the window.

Close the window.

Bar the window against 2nd story cat burglars.

What you have shown me are a bunch of strawmen with which
I have no arguments. As a result, I have no idea upon what
we disagree. Most of your technical assertions are true and
I agree with them. When you derived the same total
destructive interference equation that I had been posting,
including the negative power term, virtually all of our
arguments went away.

How about technically explaining in detail just one
mistake you think I have made? I need to understand
a mistake before I can correct it.

Here's a typical objection of yours, an implication with
no technical content.

> It is where you diverge from Hecht ... that I take issue.

I sincerely have no idea where you think I diverge from Hecht
and your refusal to enlighten me is interesting. In fact, I have
quoted Hecht extensively and borrowed some of his concepts from
optics to apply to RF. His treatments of superposition and
interference are the best I have ever read. I am not aware
of any divergence from Hecht on my part. Your assertion that I
diverge from Hecht or Richard presuming to roll Hecht's eyes
for him contains zero technical content from which I learn
nothing.

Want to know what a CCD antenna is really
supposed to do compared to say a delta loop...Just put one up and it
seems too good to be true compared to my well known hot signal 40 meter
delta...what is your opinion and please reply all so I will get a
person
response.

We already quickly talked about this a year or two ago, but
I'm not that great a fan of them. Or at least, I see no real advantage
to any other type of antenna. I've worked and check signals on scads
of those over the years, and to tell you the truth, as far as
performance
compared to just a dipole, they are often inferior in the real world.
Or to put it another way....Many of the CCD users often had inferior
signals compared to the dipole users, when you take an average
reading over a period of days or weeks.. I never saw any that were
better...
Why does it seem to good to be true? All a CDD does is supposably
maintain a more constant current distribution across the antenna.
In some cases, IE: a steep inv vee, this could be a *disadvantage*.
Or seems to me...I would prefer the current concentrated at the apex,
which is the high point of the antenna. If you spread current more
towards
lower sections of the wire, this could actually decrease perfomance.
Myself, I see no advantage, and will stick to my dipoles, etc...MK

Hi Richard,

white house marching orders were to ignore the ammo dumps (museums, relief agencies, nuke sites, industrial areas, power plants, water works, ...) to looters and to protect the energy offices in the capital.

Once the energy offices were secured, new orders to ignore the wandering deserters, stay out of the desert smuggler lanes, and avoid borders - to take command of the pipeline.

Once the pipeline was taken, new orders to ignore securing the pipeline, or protecting the fields and plants, and to shrug off the terminals and ports until Haliburton arrived.

Once Haliburton arrived, new orders to abandon military operations to protect foreign workers (from the US of course), and convert aid workers to informants for intelligence operatives (increasing the demand on the Armed Forces to protect even more civilians) and to patrol in advance of civilian operated trucking operations. Military personnel were diverted from mission to build and secure the "Green Zone," a soviet style encampment modeled after Kabul during the (failed) occupation.

Then reduce troop count.

Then raise troop count.

Then extend tours.

Then cap retirement and discharges.

Then institute rotations guaranteed for 10 years out. Not to mention being humbled into a death gratuity raise, and more pay. Quick discharge for those medically unfit due to "non-combat" injuries (a bureaucratic double shuffle).

Clearly there is absolutely no will to win. There is every will to balance this war on the back of men in uniform though and to rob the treasury to pay contractors 5 to 10 times as much to do the same work of a qualified grunt, who has to train these clowns and then take an RPG while watching their backs.

The draft dodgers and goldbricks that inhabit the administration never learned the lessons of Vietnam - they had more important things to do with their life when other men in uniform were preserving freedom and Democracy and standing against the Communist menace.

Ron, I have a 12 element Yagi for TV (Horizontal) at 529 MHz and I find tilting it down by about 10 degrees improves the reception by a noticeable amount. The ground also slopes downhill by about 12 degrees too (in the direction I'm looking). Putting the Yagi up higher is not as good as having it about two feet off the ground with the downwards tilt. The station is about 100 km away and the signal has to "bend" over a range of hills 40 km from my location.

Believe it or not, but from historical weather data. Historical wind profiles do exist. Statistical analysis will yield an 80 percentile, 90 percentile or even 99 percentile probability of all wind being below the profile limit.

Mine is sitting on a pile in the back of my yard, and replaced by
a Steppir BigIR. On 40, and 80 the Titan is nearly worthless. On
the other bands, it is marginally useful. Compared to a BigIR,
fogettaboutit (I live in Jersey now). The BigIR acts as a 3/4
wave on 15 through 6 meters.

Asimov wrote:
"How can one estimate stress cycles from a wind load?"

Tower failure usually results from a single event or cycle of overstress.

Radio towers are rated according to the mph or wind load (pounds per square foot) they will withstand while carrying all their other loads, dead or live.

Towers do vibrate in a breeze as any tower climber can affirm. Resonant frequency depends on construction.

Wind vibration has brought down structures. A famous example is "Galloping Gertie", a suspension bridge in the western U.S.A.

Deflection is limited in radio towers and elastic limits are not exceeded. The tower section returns to its original form after each flexing.

Stress cycles enlarge certain microscopic cracks. Examples are the Comet airliner. Three aircraft flew apart in mid-air. It was determined that stress cracks in the angular corners of its windows were enlarged by pressurization / depressurization cycles. This was fixed by rounded corners but it was too late. The first jet airliner was scrubbed.

Another example is found in high pressurre gas pipelines. Their internal pressure cycles and this tends to enlarge microscopic cracks, if any, in the pipe. Pipes are hydrostatically tested before placed in service (no energy storage in water as it is incompressible) so a pipe blow out of water won`t likely hurt a bystander. After the pipe is put in service it is retested each year.

Radio towers are not usually flexed beyond limits by vibration but come down due to an accident and / or extreme wind.

Best regards, Richard Harrison, KB5WZI

Yes, the Tacoma Narrows Bridge !

They forgot to design it for torsional forces.
Expensive lesson to learn.

It was rebuilt without the solid sides,
this allows the winds to pass between the
steel members instead of against them.

Hi John,

It's too bad your window does not lend itself to the spacer-with-holes
approach, as I was also going to suggest that. Does that non-removable
screen have a wide frame? If so, maybe you could go through holes
in a window spacer, then through holes in the screen frame.

In any case, you could save yourself one of those holes in the wall by
letting your "ground" wire and the coax share one hole.

Better yet, you could forget about the "ground" wire altogether--at least
if you have a third-wire ground in your AC sockets. A long "ground"
wire will be too puny and inductive to be any kind of RF ground. And
if you have a power ground through the AC socket, adding a parallel
ground path will just confuse things, increase your lightning risk, and
possibly put you into a code violation.

I have only AC-socket power grounds in my second floor shack, and
I run QRO on 80 through 10 with no problems.

Thanks for your suggestion, but among other things that sheet of plastic
would get all frosted in the winter (it gets down to 0° F here), and the
heat loss through the pane (roughly 27 X 27") would be quite large. Finally,
the window has an aluminum frame and to remove either window is a big pain.

The non-removable screen has a narrow aluminum frame. My current plan is to drill through the wood sill, and patch the holes (both interior and exterior) when I leave.

The ground wire will be about 12 feet long, so for the higher bands the ground will be ineffective unless I tune it. Actually, unless I run the end of an antenna into the shack and load it against ground, I should not need an rf ground.

Thanks for your comments and suggestions.

Please note the technical content of your posting. Once you
derived the interference equations on your own, the physical
implications are clear and you apparently cannot come up with
a disagreement between us since my conclusions were based
on those very physics energy equations that you derived from
first principles. I am not aware of any further disagreement
between us. You are welcome to discuss what you perceive as
a disagreement either here or by email.

To summarize: EM energy cannot travel at any speed except the
speed of light, cannot exist without energy, and that energy
must be conserved. If reflected energy doesn't reach the source,
it must necessarily be flowing toward the load and therefore,
must have been re-reflected (as Walter Maxwell has been saying
for decades). Having only two directions in a transmission line
makes it easy. If EM energy is not traveling in one direction,
it has to be traveling in the only other direction available.

John, you can use the wood or plastic insert without weather/winter
concerns. I used the wood insert for three years. I solved the 'winter'
problem [I'm in NH and winter temperature runs to -10F] by packing the
space with fiberglass insulation. I used about 3 inches thick and never
had a cool breeze. I had to be careful about keeping rain, etc. away fro
the fiberglass [it swallows water very easily].

Apparently that would mean the waves aren't traveling at the speed of light and it would violate his "waves cannot exist without energy" law of physics, so therefore the book is wrong. Besides, as a reference, Hecht is far more maleable. ;-)

Hi Jim,

It is far more reminiscent of his proof of total cancellation, if you
accept that total allows for several percent of non-totality.

Such vague indifference is like building the Golden Gate and finding a
gap of 40 or 50 feet in the middle. "Who's gonna' mind a couple of
percent? It spans the total bay, and THAT'S what counts!"
We have a bridge builder that wouldn't cross that bridge if he came to
it.

Just a warning to beware of dealing with N9NLU. He promised me 175 ft of RG-11 coax and I sent him a money order for it. He acknowledged receiving the money but has not sent the coax. This all occurred over a month and a half ago. He does not respond to E-mail.

I have not given up on him yet, but told him I would put out this warning.

Since the EM energy doesn't flow across the match point boundary
toward the source, it must be redistributed in other directions.
In a transmission line, there is only one other direction, i.e.
the reflected energy is re-reflected at the match point. Wave
cancellation in a transmission line redistributes the energy in
the opposite direction as constructive interference.

2815. Vertical longwire? Antenna recommendation?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-16 03:40:05 UTC
From: Elden Fenison <usenet@moondog.org>
Message-ID: <slrnddgsvb.2m9.usenet@macmini.moondog.org>
Source record: 73280

First off, let me say I've very green when it comes to the technical end of antennas. Most of the conversation in this group is way too deep for me.

I am moving into an apartment that is on the top floor of a two-story building. My deck is not only facing a large undeveloped area... but there is a large tree that is only about arm's-length off my deck. This tree is probably a good 100ft tall.

What I'm after here is HF antenna ideas. I am familiar with the idea of an end-fed (more or less horizontal) longwire antenna used in conjunction with something like an AH4 tuner. One of the problems here... if I shoot a wire up in this tree... it will be vertical. Another problem... because I'm on the second floor, there is no ground connection readily available.

I could have a vertical multi-band HF antenna on a short mast on my deck. But I'm thinking it might be advantageous to make use of this big tree right next to my deck.

I would appreciate any ideas. Thanks in advance.

Wrong. All it means is that reflected energy doesn't make it across
the match point. Seems I read that in _Reflections_ a quarter century
ago. Reflected energy traveling at the speed of light is re-reflected
at the speed of light in the opposite direction. Wave cancellation
accomplishes that feat. Regarding wave cancellation:

http://micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index
.html

"... when two waves of equal amplitude and wavelength that are 180-degrees
out of phase with each other meet, they are (canceled but) not actually
annihilated. All of the photon energy present in these waves must somehow
be recovered or redistributed in a new direction, according to the law of
energy conservation. (There are only two directions available in a transmission
line.) Instead, upon meeting, the photons are redistributed to regions that
permit constructive interference, so the effect should be considered as a
redistribution of light waves and photon energy (back toward the load) rather
than the spontaneous construction or destruction of light." (Words in parentheses
are mine added for clarity.)

==========

Elden,

Go vertical or steeply sloping. Better all-round multi-band
performance than lower horizontal long wire, specially DX at the lower
frequencies. Don't worry about the wire getting mixed up with the
tree. Just avoid direct contact with foliage. Use plastic insulated
wire. No need to bother with loading coils which will spoil the
multi-band properties. Use a tuner at the lower end of the wire near
to the transmitter. A modest ground system will suffice. Make use of

2 or 3 spaced connections to the domestic plumbing system. If possible run a wire down the outside wall of the building to a few radials. A single ground rod at the bottom end will be practically useless. Disconnect the rod and you will notice no difference. You could consider lengthening the vertical antenna by taking the wire sideways or sloping downwards from the top for an excellent 1/4-wave or 0.3-wave, inverted-L performance on 160m.

Reg, G4FGQ.

More imbalance in the balance equation passing as "totality." :-)

It is established there is "some" amount of energy in the "second"
medium (in other words, beyond the match point as I have
demonstrated); it then follows there is not a total reflection (same
demonstration), and certainly not as constructive (to what?)
interference.

Thanks for the suggestion. I've spent much of the evening reading the
ARRL "Stealth Amateur Radio" book. Interesting stuff. It appears that in
addition to the wire up in the tree, I'll also need some sort of RF
ground. Maybe shooting a very thin wire over the top of my building
would do the trick.

Another thing I'm considering rather than a wire in the tree, is a
Hustler 6-BTV on a short mast. I'm not clear as to which would be likely
to perform better. But one thing... with the Hustler I wouldn't have to
spring for an AH-4 tuner.

Source record: 73287

Beste mede amateurs,
Ik heb een vertical GPA 3 van Fritzel gekregen en die heeft een aantal (3) radialen.
Nu ga ik binnen kort verhuizen en wil die antenne zo'n 1mtr. boven de grond plaatsen en de radialen in de grond leggen (zo'n 10cm). Dit wil ik doen door ze recht naar beneden te laten lopen (ong 1 mtr dus)

Is er iemand van jullie die ervaring heeft met

a. de GPA 3
b. de plaatsing van de radialen

dank,

Juul Geleick - PE0GJG

Basicly an isolated piece of copper/alu pipe in the middle of the
radiator will convert the 2m j-pole into a 70cm collinear.
This trick will give you extra gain because it downs the angle of
radiation for that band considerable.

G3JAM (I'm told) tried to integrate a J-pole into a piece of PVC pipe,
back in 1981 via Wireles World. He was forced to find his solution
into a hairpin loop and variable coax in order to achieve easy and

correct matching.

I made one of flat alu strip placed in a pvc tube based on the G3JAM design, you find this drawing here:
http://radiogaga.e-dentify.nl/pa3abk/Townsman_uk.gif
To be honest the drawing is from a Dutch hammagazine Electron jan 1991 and is based on the principle which was outlined by G3JAM in 1981.

Also have a look at the page of pa0fbk
http://www.qsl.net/pa0fbk/hampage_uk.htm (scroll down) he is using coax and ends up into a slim design.

View it's easy to slide a piece of pipe over the radiator it's worth to try it out. Just isolate it from the radiator. It will not disturb the SWR on 2M.
Before you go, note down the signal report of a remote repeater (avoid that one which is at a angle of 35 degs on a hilltop), so you can see the difference.
Jan/pa3abk

2824. Re: GPA 3 Fritzel

There is no GPA 3 afaik, I suppose you mean the GPA 30?

> Is er iemand van jullie die ervaring heeft met
>
> a. de GPA 3

I used the during a trip to TF and OY in 2001. It works, but
that's about it. Not too much to expect from this antenna with 3
radials only, but I guess with additional radials it will
perform a lot better.

> b. de plaatsing van de radialen

At http://www.swschwedt.de/kunden/dm2ble/dok5-8.htm there are
several diagrams which show the radiation pattern at different
radial angles. Looks like 135 degrees yields the optimum gain.

My personal favorite is to get a 2" or 3" (depending on how many runs of coax you plan to have going out) plastic LB box from a home supply place. Take a hole saw of appropriate size and drill through your wall (be sure to drill between studs!! Also assuming wood construction on the house) and put in the LB box. Once you have the coax(es) run through, fill the rest of the inside of the box with fiberglas insulation to keep the bugs out. If you're worried about critters like mice, get some of the expanding foam insulation that comes in a can and fill the LB with that. Once you do that, it might be a bit difficult to add coax runs later...

What's wrong with this picture? Looking at it upside down?
With the source on the left, the second medium is to the right
(load side) of the first medium. Of course, there is energy to
the right of the match point - because of standing waves, more
energy than exists in the first medium to the left of the match point.
There's no reflected energy in the first medium to the left of the
match point. It appears to look something like my earlier example:

```
1w | 1/4WL |
laser-----air-----|---thin-film---|---glass---...
1st medium | 2nd medium | 3rd medium
n=1.0 n=1.2222 n=1.4938
Pfor=1w Pfor=1.0101w Pfor=1w
Pref=0w Pref=0.0101w Pref=0w
```

Reflected energy is eliminated at the air to thin-film interface
because of wave cancellation (total destructive interference).
According to Hecht and every other reference I've seen, the
reflected energy involved in the wave cancellation event at the
match point joins the forward wave in the 2nd medium. Of course,
that increases the amount of energy in the 2nd medium beyond what
exists in the 1st medium. The necessary (total constructive inter-
ference) energy is contained in those standing waves in the 2nd medium.

www.mellesgriot.com/products/optics/oc_2_1.htm

"Clearly, if the wavelength of the incident light and the thickness
of the film are such that a phase difference exists between reflections
of p, then reflected wavefronts interfere destructively, and overall
reflected intensity is a minimum. If the two reflections are of equal
amplitude, then this amplitude (and hence intensity) minimum will be
zero." [total destructive interference]

"In the absence of absorption or scatter, the principle of conservation
of energy indicates all 'lost' reflected intensity will appear as
enhanced intensity [constructive interference energy] in the transmitted
beam. The sum of the reflected and transmitted beam intensities is always
equal to the incident intensity. This important fact has been confirmed
experimentally." [my notes]

In the above example, the laser's transmitted beam intensity is 1w.
In the 2nd medium, the reflected beam intensity is 0.0101w. The incident
intensity upon the 3rd medium is 1.0101w. "This important fact has been
confirmed experimentally." The above example is equivalent to a
matched 1/4WL transmission line section having the following
lossless characteristics.

1w XMTR--50 ohm coax--+--1/4WL 61.2 ohm coax--+--75 ohm coax--75 ohm load
Pfor=1w Pfor=1.0101w Pfor=1w
Pref=0w Pref=0.0101w Pref=0w

Both antennas are single wires. All single wires of the same length perform the same. The only differences between the antennas are the losses on the transmission lines. The lowest loss transmission lines are open wire, or ladder line.

Regards,

Frank

2834. Quad/ beam for portables activities ?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-16 18:45:33 UTC
From: Thierry <->
Message-ID: <42d955cc$1@news.vo.lu>
Source record: 73297

Hi,

I need your advice. Here are my needs :
I'd like to DXing on portable at 100W SSB. I am looking for a directive antenna displaying an interesting gain and F/B. Another factor to consider is the price but I am not ready to build the antenna myself. The rotation of the mast/antenna will be insured manually.
I have thus to use the lightest 2-ele quad or a 3-ele beam.

My weight being close to 65 kg the weight of this antenna should be of 20 kg max (at first sight. I don't exactly know what weight I canb lift up, but probably not much)
If this is a quad I think that I can still place it 3-5m high max (the lower string being 1 to 2m over ground), for sure much higher for the beam.
The overall length of the antenna cannot exceed 4-5m and the possible boom must be telescopic or easy to assemble as all parts could enter in a medium size car (so elements to assemble must be 2.5m long max or so)

So I am looking for a dealer manufacturering light elements or collapsible antennas or easy to setup (in less than 30 min-1h)
At last I prefer a full length quad or, if that exists, a quad using traps (but I've never seen that) but the beam could use traps and the ends.
This antenna must be tuned on 20m or maybe a tri-bander 20-15-10 or 20-17-15m

Is this a dream or not ? If not, do you know some manufacturers providing such antennas ?

Excepted Hexa-Beam Light models, I don't really know other dealers (and BBQ is a shortened quad and quite heavy and Titanex sells only large beams and verticals).
Do you have some good experience in the field in erecting such /P beams ?.
If you do, what model do (did) you use ?

Thanks for your comments

I'm reading an article about antenna aperature. Is it correct to state that dipoles have a very large aperature and something like a horn assembly used in microwaves has a tiny aperature except for wavelength for which the horn is designed?

Just trying to get a handle on this advanced theory.

> Just trying to get a handle on this advanced theory.

Dipole aperture is the capture area which translates an incident field, in W/m^2, to the actual power received by the dipole. For example the aperture for a half wave dipole is 0.13(Lambda)^2, where Lambda is the wavelength in meters. A 40 m half wave dipole would therefore have an aperture of 52 m^2. A horn aperture, and also a parabolic dish, aperture is the physical area of the mouth of the horn.

Regards.

Frank

Hi Larry,
I intentionally posted the very same identical mage twice since there was no damage and no change in the image even had I taken one after the storm cleared. There was no damage here at all to the station in any way.

I NEVER realized my photographic prowess would cause such a stir which included accusations of "misrepresentation" "spoofing" "nice try" and comments about my "shit tower" "crappy installation" etc. I was even ridiculed for not "being in the eye of the hurricane". Gee maybe next time I can request a 200 mph cat 5 hurricane to plow through my backyard.

Be that as it may since human nature and the heart of man are such I simply wanted to show that there was absolutely no damage.

So to "prove" there was no damage here is a link to a snap I just took of the tower. Geesh Louise......

It may not reached that area but it was a large storm so you could get dmaging winds hundreds of miles from where the hurricane hit. While it looks like the pictures don't show damage, it could be further down.

There is zero net refraction, given by definition. So all your
refraction math was irrelevant and negated nothing. All that
exists in the example is forward energy and reflected energy
which you chose not to deal with at all.

The reason that optical engineers know so much more about power
and energy in EM waves is because that's about all they could
measure for 100 years. They don't have the luxury of measuring
the voltage in an EM light wave. And using voltage to analyze
photonic EM energy waves doesn't reveal the whole story.

2848. Vertical Radiation Pattern?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-16 23:03:25 UTC
From: jimbo <jimbo62@spamex.com>
Message-ID: <vmgCe.985$LC6.606@fe06.lga>
Source record: 73313

This may be a little off topic, but here goes anyway.

I have read somewhere that vertical antennas radiate almost nothing
below the lowest elevation of the antenna.

So, I was wondering if a wireless router also radiates almost nothing
below the router. (The antenna of a wireless router is usually
pointing up.) These devices usually operate at 2.45 GHz.

I know that routers usually have other means of security, but I was
wondering if I could also locate the router such that the radiation
was limited or non-existent in one direction.

Thanks, jimbo

>
>I have read somewhere that vertical antennas radiate almost nothing
>below the lowest elevation of the antenna.

Well, a half-wave vertical dipole in free space radiates a pattern aimed towards the horizon. There's significant radiation both above and below the horizon. There are deep nulls directly above and below the antenna, but the null isn't terribly deep once you get more than, say, 20 degrees on one side of the axis of the antenna.

>I know that routers usually have other means of security, but I was
>wondering if I could also locate the router such that the radiation
>was limited or non-existent in one direction.

I wouldn't count on this at all. Although the pattern will be weaker in the axis of the antenna, this sort of antenna system is not in free space. There are all sorts of reflections from metal objects in the building, and these will tend to fill in the nulls to some extent.

The nulling is sufficient to help reduce interference (to some extent) between access points located right above one another on different floors of a building, but it's not completely effective even at that, and should not be counted on for security or privacy.

Uh-huh. Against myself, a practicing and successful optical engineer
with optical patents; you, a xerox jockey, are comparing yourself?
:-)

Bubba, you can't even answer simple power questions like:
You have a one square cm target that is irradiated with
64 microWatts of 660nM radiation at a distance of 1M
from a light bulb. (which is less than the power reflected from
one of your example interfaces and still visibly quite bright.)

How much power is found in the 555nM spectrum expressed
in Lux?

Both are power spectrums within a 30nM BW.

How much total power is the light bulb radiating?

Optical engineers can answer this, and I will by midnight. ;-)

No one expects a binary engineer can (example of a simple 1 or 0).

Yah know, Charlie, in retrospect, the only thing that bothers me about your installation is the one guy point as shown in 100_5463.jpg . It just looks a bit unsubstantial in the picture. I would grant that maybe in person, it might seem better.... however, thanks for the offer for free airfare, but I prefer the temps here on the Oregon coast.

The wire should outperform the 6BTV by a large margin IF you have an
even half-decent counterpoise/grounding system in place like a
wire-over-the-roof plus Reg's plumbing system connections. You'd also
get much more bandwidth with a wire vs. the 6BTV. A random wire can be
used on 30M, a 6BTV cannot be used on 30M, etc.

> But one thing... with the Hustler I wouldn't have to
> spring for an AH-4 tuner.

You can put up a wire and buy a manual wire tuner like the $110 MFJ
941E plus the cost of the wire. I'll do the tuning manually and save
$150-200 additional cost for any autotuner every time.

Oops, my bad, you can use a 6BTV on 30M. But you can't use it on 17M or
12M. A wire can be tuned to operate anywhere in the HF spectrum and
beyond on both ends.

Most of the reflection examples in _Optics_, by Hecht, assume
zero net refraction and I will continue to follow Hecht's lead.
(Complicating examples beyond what is needed for understanding
the principles involved is a form of obfuscation.)

Richard Clark, KB7GHQ wrote:
"No one expects a binary engineer can (answer that)."

I have a different take on reflection of the reflected wave at the generator. I think current results from potential difference. When there is no difference, there is no current.

Suppose you have an ideal transformer with a perfectly centertapped secondary. Volts are the same on both sides of the centettap but 180-degrees out of phase with respect to the centertap. Connect the extremes together and a high current results from the short circuit.

Suppose you modify the secondary by untwisting the sentertap and this results in two identical secondary coils. Connect these in the same phase in parallel. No current flows between the coils because no potential difference ever exists between the coils.

An ideal transmission line with a complete reflection at its far end is much like the transformer with two identical secondaries. The incident and reflected voltages are equal and at some points can completely add or subtract.

Back at the generator connected to a line with a complete reflection at the load end, there are line lengths which produces a reflection arriving back at the generator 180-degrees out of phase with the generator voltage. This produces the equivalent of a short circuit on the generator.

If line length results in reflected volts exactly in-phase with generated volts, no current flows into the line once steady-state conditions are established. This is what happens in the short-circuited 1/4-wave stub (metal insulator). It is the standoff between identical voltages which produces the extremely high impedance at the input to the stub.

I have not tried my Bird wattmeter on this. Maybe Cecil has and will say I am wrong.

Best regards, Richard Harrison, KB5WZI

==========
Neither of them is anywhere near as good as a random length dipole fed
over a 450 or 600 ohm transmission line, with a tuner.

A so-called half-size G5RV is a laughing stock.

wrote:

>Most of the reflection examples in _Optics_, by Hecht

Dear Readers, it isn't midnight and there is no chance that our scribbler has actually had the experience to express any solution bearing on power but his own cooked theory. After-all if we can see the reflections from these anti-reflective layers, and that is sufficient proof to invalidate this folderol; well, experience must be a lie compared to tarted up references (which is so much sacred hamburger).

So, for the sake of those following this (and sufficiently wise enough not to jump into this sewer without a snorkel), I posed a simple question as to the amount of power in the 555nM band (within a 30nM BW) given a known power of 64microWatts illuminating a square cM target. I further asked that this be expressed in Lux.

Well, this problem is no more difficult than being able to simply take the one power already known, the characteristic of a tungsten lamp and transforming it into the other wavelength. This is a commonplace of optical engineering unknown to the binary engineer who finds the sum total of his entire instruction in two pages xeroxed from a library book.

I will skip the expression in Lux simply because that would be showing off, and cut to the chase of power expressed in conventional terms (the binary engineer will be wholly lost in the arcana of practical measures of light and couldn't be trusted to answer if any power were actually visible - commonplace experience is a mystery) = 220 nW.

This answer reveals there is more to the characteristic of the tungsten lamp, than meets the eye. 220 nW is actually quite bright, and yet we are being handed sloppy work that is acknowledged to dismiss nearly a thousand times as much power as a trivial difference that doesn't invalidate a claim of "total" cancellation. I wouldn't trust such a personality as a bank teller, nor a goldsmith, nor a surgeon, bridge builder, ... in short, no one serious about the subject. This kind of slop is what CFA and EH antennas are built from.

So, this practiced optical engineer has delivered what the binary engineer could not. Nothing amazing about that - experience clearly differentiates knowledge from wishing. I could continue with turning this into Lux/Lumens/Foot-Candles/Candelas (terms of confusion to our

scribbler), shifting the wavelength again, expressing the total power radiated, expressing the total light seen (or power in the BW selected light), and so on that are complete mysteries that utterly wipe out these facades breathlessly offered as compelling proofs.

The single most embarrassing question I've offered to this correlation of "glare-proof" optics was to ask the obvious:
What wavelength is Glare?

Even here there is a practical answer that stumps the binary mentality limited by the lack of experience, and the dearth of exposition from two pages of thumb worn xeroxes.

So, we have these "Can you solve this?" howlers where the author is so utterly unversed on the topic that he cannot describe power; fails to acknowledge if that glare's reflection could be seen at the typical values found in perfect math solutions; what wavelength we are talking about; why the problem is posed out to 5 places of precision and with only 1 place of accuracy results; why a light level of 1/1000th of the typical perfect math solution is still visible but is dismissed as a correct result.

It has been amusing nonetheless.

Yeah, $140 difference. Question about that though... wouldn't the AH-4
be a better choice for another reason? That reason being that the AH-4
is designed to connect to the wire directly at the feed point, whereas
the MFJ is apparently designed for in-shack use.

Hi all,
For years I lived in an apartment and just had antenna's in the attic , but now having moved to a house in a few months I'll be putting up a 10-160 wire type antenna in my trees. Given the recent spate of serious thunderstorms, and the accompanying lightning, I'm a bit concerned about properly grouding the antenna so that I don't fry the house *smile*. I know about some articles on the ARRL site, but was wondering if anyone else had some ideas or pointers on how to practically do this ?

> I am wrong.

No, I agree with your analysis, Richard, as far as it goes
but an expanded look will reveal some interesting facts.

Concerning open-circuited or short-circuited transmission
lines, if the voltages add up to zero, that looks like a short,
and current is at a maximum. If the currents add up to zero,
that looks like an open and the voltage is at a maximum. If
these conditions occur at the source, 100% re-reflection of
the incident reflected wave energy is guaranteed. The Bird
reads equal forward and reflected power all up and down the
feedline.

If an open-circuited 1/2WL of 50 ohm lossless feedline is
connected to a simple class-A source having a series source
impedance of 50 ohms and a voltage source of 141.4v (as in
W7EL's "Food For Thought #1) the steady-state impedance seen
by the source is an open-circuit so the source voltage is
141.4v and the source current is 0 amps. The implication is
that it is like having nothing connected at all but that's
not correct. Measuring the current at the mid-point of that
1/2WL of feedline will prove the feedline is filled with
EM wave energy which must travel at the speed of light.

The Bird will read 100w forward and 100 reflected on the
feedline. An RF current meter at the center of that 1/2WL
of feedline will read 2.828 amps. That's the sum of the
forward current and reflected current in phase, 1.414 amps
in the forward direction and 1.414 amps in the rearward
direction. 1.414^2*50 = 100w for both forward and reflected
powers. The Bird is right. Those powers are really there
supporting the forward and reflected waves and cannot be
used for any other purpose. Since the feedline is lossless,
there's no lost energy to replace so the source power output
is zero. Anything else would violate the conservation of
energy principle. Note that at the above current maximum
point, the net flow of energy is zero since the Poynting
vectors for forward and reflected power add up to zero.

The half-size G5RV is 1.5WL on 10m and the matching
feedline section is 0.5WL on 10m, a pretty good 10m
antenna with multiple radiation lobes.

It is 0.75WL on 20m fed with a 0.25WL matching
section. The Smith Chart says that's not a bad match.

It is 0.375WL on 40m fed with a 0.125WL matching
section. The Smith Chart says that's not a bad match.

Following exactly the same reasoning, if we can measure loss in
all transmission lines, the concept of a lossless transmission
line is also folderol. The example I gave was designed for
clarity of understanding. If you choose to obfuscate clarity,
don't expect me to join you.

That's a very good concern to have!

I'd encourage you to consult with a local professional (electrician)
who is familar with your local conditions (weather, soil, electrical,
and legal).

> I
>know about some articles on the ARRL site, but was wondering if anyone
>else had some ideas or pointers on how to practically do this ?

You might find it useful to review the following document:

http://www.radagast.org/~dplatt/hamradio/mil-hdbk-419a-grounding.pdf

It's probably got more information than you want or need, but some
sections of it could be quite useful in planning your system.

Understanding the requirements of your local electrical code (which is
probably based in large part on the National Electric Code) would also
be a good idea. The text of the NEC isn't available online as far as
I know (it's copyrighted) but I understand that most good libraries
should have a copy.

The basic approach you'd want to take, I believe, is to make sure that
the feedline is well grounded immediately before it enters your
building. You'll probably want to hammer in a new ground rod at this
location, in order to keep the distance between grounding point and
ground to a minimum, and if you do so you should/must install a
heavy-gauge "bonding" wire between this ground rod and your building's
main grounding point (probably at the electrical service entrance).

Installing lightning/surge suppressors of one sort or another in the
feedline at the grounding point would also be a good idea. They might
help shunt away a high-voltage spike, induced by a nearby lighting
strike, which could damage your equipment.

If your shack is not on the first floor, it'd probably be a good idea
for you to run the feedline down the wall to ground level, ground it
there, and then run it to the antenna.

You might want to consider an arrangement in which the antenna feedline drops down from the feedpoint to ground level, is connected to a ground rod at that point, and then runs along or through the ground to your house (use a "direct bury" coax, in this case, to avoid contamination of the cable by soil moisture and chemicals!). This could help keep direct- or near-direct-strike current away from your house.

One of the best things you can do is to have some sort of easy-access connector coupling, located outside the house (e.g. at the grounding block). If a storm seems imminent, or any time you won't be using the rig for a while, disconnect the end of the antenna feedline and toss it away from the house.

2881. Resistor Frequency Response

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-17 17:01:48 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <dbe2tscja1@nwrdmz03.dmz.ncs.ea.ibs-infra.bt.com>
Source record: 73246

FREQUENCY RESPONSE OF RESISTORS.

Program METALFLM.exe 41 Kbytes.

This program models small low-wattage wire-ended resistors including spiralled metal-film resistors. The model's equivalent circuit is a chain of T and L networks. Values of lumped inductance and stray capacitance are estimated by the program from the component's physical dimensions.

The component with it's terminating leads is treated as a lumped L and C non-uniform transmission line. The program computes input impedance from 10 KHz up to 5 GHz with the other end grounded. Fast and slow frequency sweeps are available to observe maxima and minima of Zin.

Max and min Zin are approximately related to the physical length of the component, including connecting leads, but occur at frequencies far higher than the usual and useful working frequency range.

The reflection cefficient and standing-wave-ratio are calculated with reference to Zo, Zo being the DC value of the resistor. The usefulness of the component as a dummy load or for other purposes at any frequency can then be ascertained.

The effectiveness versus frequency of solid carbon-rod resistors and multi-turn UHF chokes, which are of similar wire-end construction, can also be determined. Chokes can be wound over the bodies of high-value wire-ended resistors, the parallel resistance value perhaps having some desirable effect on the ultimate response.

Another use for resistors having a good high frequency response, or at least a known frequency response, is for ratio arms and switched resistors in impedance bridges and other measuring instruments.

Download METALFLM in a few seconds and run immediately.

On Sun, 17 Jul 2005 07:55:32 -0500, Cecil Moore <w5dxp@hotmail.com>
wrote:

>The example I gave was designed for clarity of understanding.
It is a poor example of understanding when you purposely inject error.
There is nothing clear about intentional mistakes. Any rejection of a
complete solution is a suspect agenda from the beginning.

Understanding does not come of clouded data and murky results. What
has been offered is evidence of poor knowledge, and no experience.
That poor foundation built on sand has translated into outrageous
conclusions that are nothing more than castles in the sky.

I can demonstrate this in that when posed with a REAL power
application, silence typically falls for the simplest of computations.
Like how much power does a light bulb radiate to illuminate in the
660nM region a target of 1 cm square, at 1 M with 64 microWatts/30 nM
of bandwidth?

The inability to do such trivial power models reveals every thing else
offered has the makings of superstition that builds CFAs and their
ilk.

Dear Readers,

Knowing the binary result beforehand (0) to this simple appeal, I will
render that answer before the day is out. It will exhibit how little
optical knowledge is contained in this "Can you solve this" banality.

You may all note that my embarrassing question:
What is the wavelength of Glare?
remains without comment or response, even though there is a practical
answer and a perfectly reasonable explanation. The gulf of silence
that attends this remarks how complete the void of experience is. Can
you imagine basing an entire exposition around such a commonplace
problem and not knowing the basics? In short, this "Can you solve
this?" is more an appeal for knowledge than a demonstration of skill.
For one, you need to know WHO needs this glare cancellation capacity,
and then you would ask WHY; and it then follows that the wavelength
falls within these particular aspects. Fairly simple stuff for the
optical engineer, but wholly outside of the binary engineer's
experience and education.

The greater embarrassment is that apparently it is outside of the
skill of performing a simple Google search to fill that gap of
knowledge. As I offered, once that knowledge came to mind, the WHY
and WHO would explain the WHEREFORE instead of this rummaging through

text to xerox formulas to force-fit a presumed theory of "total"
cancellation.

It is still entertaining tho', as a burlesque of engineering. ;-)

Hi Reg,

Thanks for making more of your handiwork available to the group!

Any idea how the model predictions track with real-world measure-
ments on various kinds of resistors?

Many years back in our GTE (now Verizon) RF development lab,
we found that we could make much better impromptu RF terminations
using big 2W carbon resistors than with the smaller sizes. It seems
the internal carbon rod was closer to the surrounding BNC connector,
thus producing less of an impedance bump. These impromptu loads
worked fine to beyond 500 MHz if the "outside" lead was just bent
over and soldered to the connector shell. But if a metal disk was used
between the lead and shell, the upper end was extended to 1+ GHz.
(Shouldn't try to push a BNC beyond that anyway!)

Hi Jerry,

Dave's comments are accurate and helpful, in almost every case.
But there is the possibility of a very substantial simplification here.

The Key Question: Do you need or want to operate your rig during
electrical storms?

If the answer is YES, then you better do everything Dave suggests--
and possibly a whole lot more. Praying a little might also be helpful.

But if the answer is NO, then you would probably do just fine
(with respect to antenna-specific risk) using the last suggestion only:

> One of the best things you can do is to have some sort of easy-access
> connector coupling, located outside the house (e.g. at the grounding
> block). If a storm seems imminent, or any time you won't be using the
> rig for a while, disconnect the end of the antenna feedline and toss
> it away from the house.

The main thing to remember on this one is that the more CONVENIENT
you make your disconnect, the more likely it will be that you'll actually
USE it appropriately.

Uhhhh, Reg...

Don't look now, but:

1. The equations underlying the Smith Chart don't become more
valid when they are programmed into a computer.

2. Antennas scale with frequency, as you are undoubtedly aware.
So a half-size antenna used at twice the frequency is neither
more nor less "ridiculous" than the "full-sized" version.

3. The "not bad" matches Cecil was talking about were/are
achieved WITHOUT the use of an outboard antenna tuner.
So our hypothetical G5RV/2 DX chaser just might bag the
quarry while you are still getting your tuner on frequency.

For a receiving antenna, a coherer provides excellent lightning
protection.

Unfortuantly, on a transmitting antenna, the rf would immediately make
the coherer conductive and a direct short to ground (perhaps very low
QRP power could be used?)

One can easily be construted with a bottle filled with metal filings,
two bare wires are inserted into the filings (not touching and
seperated by a substantial amount of the filings), one wire goes to a
good earth ground, the other to the antenna.

If the coherer shorts to ground it only needs to be shaken to reset (I
would suspect in a real lightning strike the metal would be fused,
quite possibly even vaporized.)

I have a 10-80 wire connected between 3 trees. It's fed with
ladderline. Lightning protection is simple -- with banana plugs and
jacks, I can unplug the ladderline just outside the window whenever it
looks rainy.

You might think about whether you want to use coax or some kind of
balanced line -- balanced line is a simple disconnect.

Hi Roger,

Indeed, I know the spiderbeam since the very beginning but it is really too
huge I believe
I list all "portable" multibands solution in this excel file
http://www.astrosurf.org/lombry/qsl-portable3.htm

From what I have seen or read, most portable beam are working on 6m or
below.
Remain the quad that works fine closer to the ground than the beam.
Hard to find.

Hi there, Op...

Well, the devil is in the details, isn't it?

One "compromise" from a Mercedes is a Yugo.
That would be a pretty big come-down.

But another "compromise" from a Mercedes would be a BMW
(or vice-versa). That wouldn't be hard to take at all.

Presumably, the reference antennas against which the G5RV is
called a "compromise" are full-sized dipoles for the respective
bands. IF the G5RV can come reasonably close to those
(and many users seem to think it can), then there is a pretty
good basis for its enduring popularity.

"I know about some articles on the ARRL site, but was wondering if anyone else had some ideas or pointers on how to pratically do this?"

Coax helps protect your radio from lightning. It rejects common-mode currents inside which might otherwise damage the radio.

Thunderstorms often produce lightning from clouds charged to 100 million volts with respect to the earth. Current may oscilate up to 200 thousand amps in a lightning discharge. Temperature inside the stroke may reach 30 thousand degrees C (5x the temperature of the sun`s surface).

A stroke starts and stops abruptly, so it contains r-f in addition to d-c. The discharge may take up to 150 milliseconds and consist of several flashes in both directions. It may include a path miles long, so it has a pretty good ionization trail for an antenna.

If your antenna is struck by lightning, it is best to bypass the energy aroundb people and equipment.

Medium wave stations have arc-gaps around the tower base insulators, Faraday screens between primary and secondary of tower r-f coupling transformers, and tower lighting chokes which keep both r-f and lightning out of the power mains.

High frequency stations often use balanced wire lines, and these have an arc-gap from each wire to the earth at a point outside the station.

VHF, UHF, and microwave stations use grounded antennas and coax. Towers which support the antenna generally have each tower leg separately grounded by a heavy cable to its own ground rod near the tower base. R-F cables and waveguide are grounded at the antenna and at least at the base of the tower. Coax nay be coiled with several turns between the tower base and the shack to discourage lightning on the outside of the coax from entry to the shack. Waveguide is solidly bonded to the tower but not usually coiled to make a lightning choke.

The solid-state VHF, UHF, or microwave station often needs additional surge protection because of the difference in potential between electric service and antenna system grounds
This takes the form of husky r-f chokes in each power wire to the r-f equipment. Each choke is shunted at each end to ground with a capacitor and with a voltage limiting device or devices, often MOV`s. There are ready-made brute force coil and capacitor low-pass pi-filters which need only addition of MOV`s to make them effective lightning suppressors. I made mine in an earlier time using Miller Coil Company tower lighting chokes and they worked well. You could wind 2 or 3 dozen turns of #12 or

#14 insulated wire in an 8-in. dia. circle to make your own 0.1 millihenry chokes. The standard choke used to be 2.5 millihenry, but it is not critical.

The same wiring techniques required for noise reduction apply to the biggest noise of all, lightning.

Best regards, Richard Harrison, KB5WZI

An interesting fact that many don't know is that lightning actually
strkes upwards as the clouds are negatively charged.

The full size G5RV IS A 20 Meter antenna!! That's a fact.

It performs as designed on 20 meters!!

Any wire can be made to radiate on other frequencies by using stubs, baluns, tuners, etc. But that does not change the fact that the G5RV is designed as a 20 meter antenna!!

It works on other harmonically related bands, but it is still a 20 meter design!

I used one about 6 years ago. Then changed to a center fed doublet with open wire tuned feeders. I'll take the doublet/tuned feeders any day!

Agree! But, I still lost an ICOM 756 Pro II when disconnected from
antenna,
and had the power supply unplugged. A ground loop in the external ground on
the 756 and the power supply, where 12 volt return is tied to chassis,
caused
damage to the power connector on the 756 and fried the 756 internal
cabling and
circuit boards were carbonized.

I'm still waiting for my insurance settlement.

Ok Brian. I appreciate the advice you've given. I do understand that
there sometimes is disagreement between hams regarding certain things,
like having a portion of a radiating element in the shack.

Personally, I think I'd opt for an outdoor-mounted AH-4 for reasons of
efficency, convenience, and safety. But it is nice to know that other
options exist. So right now, my preferred solution is an ICOM IC-718,
with an AH-4 and a longwire. I think that should work nicely.

After surveying the new apartment location a little more closely, looks
like I could run a horizontal longwire, roughly parallel to the ground
for 100ft into a tree with some sort of insulator on the end. Then I
would do the "in apartment" counterpoise/RF ground. This would probably
be about 20/30ft off the ground... second floor height.

Regarding your explanation for getting various wires from indoor to
outdoor, I've taken the exact same approach. Using a thin 2x2 in the
window with cables running in through an opening in it. Seems to work ok
and no permanent holes in the structure.

Dear Larry,

There's nothing to show - it's too simple for a picture. You just take a 1/2 wavelength of horizontal antenna and you end-feed it from one side of a piece of balanced line 1/4 wavelength long. You then link couple that to the final tank coil and do your matching with the swinging link and the tank circuit. No equations, no schematics or pictures - just do it!

Source record: 73267

Hi Ed.

Regarding your big 2-watt carbon resistors at 500 MHz -

what values of reflection coefficient or SWR were experienced when you say they "worked fine". Can you remember? Or did you have some other way of assessing "fine" performance?

The DC value has to be allowed a resonably large tolerance about its nominal value and the HF performance cannot be any better than that.

Reg, G4FGQ

Hi Reg,

Our definition of "worked fine" was that the measured SWR was
consistent with the rated DC resistance and tolerance. As I recall,
we were using 51 Ohm 5% resistors. Typical SWR was under
1.1 up to 100 MHz, and 1.2 to 1.3 at 500 MHz for the bent-lead
(lesser performing) version.

These loads were just for handy lab use, and were not products or
calibrated test equipment, of course.

Ed

>of bandwidth?

Dear Readers,

It comes as no great surprise that this simple example of optical
power is so powerfully baffling to a neophyte. Optical studies are
not nearly as simple as some might believe, and on the other hand, the
field yields answers as easily as any if you simply observe first
principles.

Those principles are as simple as knowing the area of the total
surface illuminated by the standard light bulb (we will ignore the
shadow cast by the base). This is quite easily determined as I
already offered the distance of 1M and the equivalent power within a
1cM area of that total surface.

The math is hardly as arcane as "interference math," but as I have
demonstrated how poorly that was performed, perhaps a little walk
through here is in order.

The area of sphere, at 1M radius quickly resolves to 4ï¿½pi Mï¿½.
Conversion to cMï¿½ "should" be a knock off, but when you use 5 place
math to perform 1 place accurate results.... Well, let's just cut to
the chase and skip all the so obviously difficult parts and just
answer the question above.

Our source is a 10W bulb. Common, mud-ordinary situation offering
smaller values of power than supposedly encountered in the
"reflections" of this "Can you solve this?" drek. And as I offered,
such reflections as you would observe (much like the mathematical
impossibility of a bee's flight) - quite bright.

However, this was on scale with 1cMï¿½ and when the original question
posed a 1W laser - well you can appreciate that I do not hesitate to
point out that the power of those "totally" cancelled reflections are
easily 10,000 time brighter than my insipid Christmas tree bulb - and
AT LEAST 10 TIMES BRIGHTER THAN THE SUN!

One must truly imagine quite hard to dismiss such brilliance as being
"totally" canceled out to the point of invisibility. :-)

It has been enjoyable, and yet there are questions remaining that relate to the point of this origin in "Glare." I notice that this too draws a vacuum of response and yet it was so central to "illustrating" a thesis. No wonder such papers find their way to the round file at the editor's desk. The only chance for publication, however, is strictly meeting the academic strictures of a vanity press - its vaudeville quality. In this regard, the opus of "total cancellation" is destined for serialization and possibly a Hollywood movie for next summer. Myself, I enjoyed the new "Hitchhiker's Guide to the Galaxy," but I found the new Ford Prefect rather lame. Oh well, I went to the matinee showing to save a buck or two - so let's call it break-even.

A major problem for pipelines are where both corrision and cracks are within limits but close to each other. The pipeline folks have been analyzing and fixing those for over a decade now.

Retesting is not done by pressure, as far as I know, but by sending "pigs" down the line to analyze the pipeline.

And I bought the whole kit in America for almost half price
car adaptor
stand alone fast charger
speaker mic
extra battery
programming software and cable
soft case
a smaller comet antenna
a bnc/sma adaptor
barometer altimeter board
$537
and already had a 110v converter ☺1

For sure, as soon as there is a sink, a path of lower resistance, the
lightning will find it and will follow it to your most expensive accessory..
This canal can be the coaxial, the house cabling system, even yourself if by
mistake you touch a metallic device during the thunder. Even the ground as
state in my article can be an excellent way for the lightning to strike your
installation. Hence it is better to entrust this installation to experts.

So I when I say to unplug all devices, this is *all* cabling system,
including grouding.

Usually the insurance do an excellent job and you should be able to rebuy
all your defective devices.

Good luck.

I haven't use the half-size models which are too small to give good results,
excepted for local QSO (and dxing with luck during high solar cycle, hi!)
I am not sure that your solution will be efficient, even on 15 or 20m.
All depend on what you want to do with it and on what band.

I used both in full-length and I prefer the reception pattern of the windom
that fills the gaps not covered by the dipole due to its vertical segment.
The overall performance is better that using a G5RV close to the same
length.

Here is some impressions when I used both :
http://www.astrosurf.org/lombry/qsl-antenna3.htm (second half of page)
and here http://www.astrosurf.org/lombry/qsl-g5rv.htm for some diagram
patterns of the G5RV.

Thanks Ed for the information. I need time to think about it.

At first sight your data falls in the same ball park as that generated by program METALFLM below 500 MHz. Ball-park accuracy is all that anybody can expect under the circumstances.

It is a fact that program METALFLM is the first of many programs I have ever produced without the support of personal measurement experience. I have very little practical experience of frequency response of resistors above above 30 MHz and not very much below that.

But I DO have confidence in my assessment of L and C values as calculated from physical resistor dimensions. Also I have confidence in my ability to model equivalent circuits of distributed L, C and R components.

In the end, all that's needed. are the limits of reflection coefficients versus frequency for ordinary wire-end resistors mounted on circuit boards.

And of course, rubbish in = rubbish out.

Cecil, is there an IEEE definition of "Ball Park Accuracy" ? I'm on South African red. Gone off Californian white.

Reg, G4FGQ

By the way, the program has brought to light the fact that board-mounted resistors in the range 100 to 400 ohms have a slightly better frequency response than those around 50 ohms. Therefore, wideband 50-ohm dummy loads are best made from a nunber of higher value resistors connected in parallel. Avoid series connections. Which is what most people do anyway.

Cecil, W5DXP wrote:
"Concerning open-circuited or short-circuited transmission lines, if the voltages add up to zero, that looks like a short, and current is at a maximum. If these conditions occur at the source, 100% re-reflection of the incident reflected wave energy is guaranteed. The Bird reads equal forward and reflected power all up and down the feedline."

Yes. A bird is indicatihg power in one direction only and this is the same along a low-loss line everywhere along the line regardless of SWR.

A short does not kill line energy. It merely transfers electric field energy into the magnetic field for an instant producing an SWR in which voltage and current patterns are 90-degrees apart.

When the load end of a transmission line is shorted, 100% of the incident wave is reflected but the reflected wave has a complete reversal in phase of its voltage with no change in the phase of its associated current.

When the load end of a transmission line is open-circuited, 100% of the incident wave is reflected but the reflected wave has a complete reversal in the phase of its current with no change in the phase of its associated voltage.

When the source end of a transmission line is effectively a short or open circuit, ir re-reflects the reflected wave.

No surprise. Hydrostatic testing pressurized pipes to maximum pressure or slightly more to prove their safety. This itself tends to aggravate cracks.

A pig is a carriage (usually wheeless and propelled by differential pressure) through the pipe. They serve many purposes. They can be used for video inspections, ultrasonic tests, or X-ray review of a pipe.

When I was a pipeliner, they were often blown through a pipe to clear it of trash and liquids.

Yeah, everybody has different opinions and experiences with this topic.
Personally I've never had a problem in the shack with wires that I
didn't also have when using a coax-fed antenna which is located
anywhere near the shack. Maybe I'll get a dose of it eventually and
have to eat my words.

I dunno . . I'd expect a wire strung vertically as far as possible up
into that 100 ft tree to work a *whole* lot better than a low
horizontal wire even if the vertical is shorter.

Keep in mind that trees move around and the wire will be tensioned or
droop when the wind is up. I've had a couple wires break and I've also
had one dipole drop because the rope running from the end of the
antenna to ground level wore thru. Another discussion.

Franklin, defying the gods, performed his kite flying experiment in June of 1752, and by late June or July, the first "lightning rods" were installed on structures in Philadelphia. Ol' Ben kinda made up his own "nec code".

Hi again, Ham Op -

You're one step ahead of me re the G5RV in that you have
used one. I have not. I see no reason to doubt your (inferred)
statement that you were only satisfied with it on 20m.

However, the ARRL antenna book lists the G5RV in the chapter
on Multiband Antennas, and begins the description as follows:
"A multiband antenna that does not require a lot of space, is simple
to construct, and is low in cost is the G5RV." (To be fair, the ARRL
piece goes on to state that 20m is the most-favored band in the
G5RV design.)

A common-sense question would be: Why would Varney design
a single-band 20m doublet that is bigger and more complicated
than a single-band 20m dipole, unless he was looking for some
added benefit--e.g., multiband operation? Alas, I don't have ready
access to Varney's old articles, so his thought process will have to
remain unknown to me for the time being.

I have no wish to assume the role of Chief Defender of the G5RV.
I merely responded to some G5RV/2 criticisms that I found illogical.
My dipoles are of the trap and fan variety, and I like them that way.

If I go off the reservation to another type of wire antenna, it won't
be either a Windom or a G5RV; I'd like to experiment with a
multiresonant OCF design. (I really don't want to bring antenna
tuners into my mix--either the conventional lumped-constant type,
or Cecil's variable-line-length type.) I like "instant" QSY+QRO.
Your mileage may vary.

Good DX,

Anonymous Handle (just for grins)

Are we then supposed to infer that it [the source] doesn't re-reflect
the wave if anything other than a short or open circuit appears there?

So it follows that measuring voltage at the wall outlet proves there's energy filling the wall. As always, it's important to remember that any such energy would of course be traveling at the speed of light - and no faster. :-)

> The Bird will read 100w forward and 100 reflected on the

Noting of course that EM energy can't normally put itself back into the source after it's done bouncing around. So, since there's no load and the system is lossless, no energy is produced or transferred, which means zero power. In this instance, the readings on the Bird wattmeter are not at all helpful toward understanding the flow of EM energy - which as Cecil is always kind enough to remind us, travels not just at any speed, but at the speed of light.

The reflection may be incomplete unless either a hard short or complete
open-circuit appears at the source where the generator meets the
transmission line. If the source appears as a complete short or open the
reflection is total.

Best regards, Richard Harrison, KB5WZI.

> are mine added for clarity.)

Interesting to note that the interference phenomenon is often described
as a redistribution, but is never described in any reference as a

reflection, or re-reflection as you have done. The reason is that when light destructively interferes in some direction, it simply does not go in that direction. It doesn't, contrary to your assertion, first go in the reflected direction, say oooops, then turn around in mid-air and go in the other direction. The reflection is prevented. Comprende senor? The Bird wattmeter can be misleading in this regard. It measures the effect of a field (sometimes like the one in Born and Wolf that doesn't have transfer of energy associated with it), and in every case assumes energy and power. But it's simple minded so it has an excuse.

Dear Readers,

Taking a deep breath and wading into the hits found at Google comes
one very typical observation:

" The methods discussed above will work with varying degrees of
success, depending on the details of the manufacturer's process.
The glare reduction factors claimed by many manufacturers should
not be taken too seriously. Some claim glare reduction factors of
up to 250 to 1. Such numbers are either dreamed up in the
advertising department or are the result of unrealistic test
conditions. A good quality anti-glare filter with a multi-layer
optical coating will reduce glare and reflections by about a
factor of 20. Visually compare glare reductions before you buy
anything."

I leave the WHO undisclosed (being it is such a tantalizing overture
to yet another, unanswerable question). We may all note that what is
described here is "multi-layer" which suggests more than one layer for
more than one BW of glare components (yet another tantalizing,
unanswerable question: What wavelength is Glare?). I will pose that
the necessity for multiple layers is derived from the same need for
one (which is actually quite useless in ordinary life).

As I offered, this is all a very common arena for the optical
engineer, and thin-films are tools for SPECIFIC needs (the WHEREFOR,
or yet another tantalizing, unanswerable question whose origin is one
of practicality) rather than as sacred cows for the theory of
moonbeams.

There are correlatives in RF and antennas such that this is not an
alien discussion. However, it takes little more effort to be correct
instead of simply clowning through the math, because these side-show
results we have been subjected with can be stretched to cover any kind
of bizarre theory. As the final line of the quote above suggests:
"Visually compare glare reductions before you buy anything."
rather ordinary advice that is so aggressively shunned by, instead,
shoveling formulas at us instead.

Richard, we both know that a transportation vehicle makes a pretty good
Faraday[sp?] Cage.

Lightning attaching to a wire will instantly vaporize the wire.

Physical damage is generally caused by direct strike. The energy in the
action intergral [I^2*R*dt] generates local heat. The thermal shock
causes the damage. [And fire].

Source record: 73195

I had the experience of a direct hit to my antenna. It was a 130 foot cage fed with ladderline. Coax was used the last 20 feet to bring it into the house.

Inside I had a TS-440, a TS-820 and an MFJ 989C.

The bolt destroyed the side of the antenna that went to the shield of the coax, the largest remaining piece was about 3" in length with most of it vaporized. The ladderline was vaporized, the other half of the dipole was untouched.

The coax split open like a hotdog put in a microwave. The same stroke went into the electric utilities and blew every electronic device in the house except a cheap GE clock radio.

A stroke went through the wiring in the ceiling and the explosive expansion of hot air blew all the vinyl siding off the front and one side of the house.

The only fire damage was a small burn mark on the shack carpet where the coax laid on the floor.

All antennas were grounded via the antenna switch and all ham gear was unplugged. All antennas had blitzbuggs and coiled coax before entering the house. These were tied to both RF ground and the single point electrical ground.

What was strange was the stroke following paths along wood beams while ignoring good conducting copper wires 3 feet away. The only damage to the ham gear was a burn mark and heat distortion on the rear panel of the tuner. It's operation was unaffected.

Hmmm. I wonder if the phase change on re-reflection the same as it does on reflection. If it does, and the transmission line is a half wave long, the Bird wattmeter readings would be real hard to explain.

And isn't it true that if there were actually a real hard short or a complete open circuit at the source, there wouldn't even be a signal on the transmission line?

2932. Affordable HF antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-18 20:49:31 UTC
From: Jerry <joxendi@bellsouth.net>
Message-ID: <jAUCe.99834$qm.31465@bignews5.bellsouth.net>
Source record: 73196

Not to "knock" the name brands in HF mobile, but have you ever wondered why they cost so much--up to 700 bucks for a screwdriver all-band mobile antenna? I do because I couln't AFFORD to pay 5-7 hundred bucks for a mobile HF antenna! And it's not the performance you are paying for; it's fancy paint jobs and "consumer" gimmickry that run the price up! And, actually the performance *may* be not be all that good anyway. Take for example the ones that claim 160-10 Meter coverage. Take a look at the loading coil, yeah, the 1 1/2" one. The one that is "transformer-wound" with ultra thin wire. THAT'S how they are doing it. Also, many times 160 meter mobile performance isn't all that spectactular anyway.

That is why I build the Carolina Cyclone screwdriver. I knew what I would want *if* I were in the market for a screwdriver that would run with the big boys, but wouldn't break the budget. Here is a 2" diameter screwdriver that does "outtalk" those "all-band" units and it does it with large diameter wire (14 gauge) and 8 turns spacing--about 1 wire diameter in between. The result is an HF mobile antenna that delivers coverage from 80 thru 10 Meters with a solid, reliable signal even when conditions
squash other mobiles. That includes the "transformer-wound" ones. For the guys that spend a lot of time on 80 and 40 Meters, I build and recommend the Cyclone II, a 3" diameter coil. It's for the fellas that spend a lot of time on these bands. It earns its keep everytime. It's what I have on my pickup truck.

I don't know it all, but I've done a LOT of experimenting and I have found that, for the best performance on the lower bands, 3 inches is about the best overall. If you go much bigger, then the "Q" goes so high and the bandwidth so narrow, you spend much time re-tuning as you drive along. I once tried out a 6" bugcatcher, and you couldn't move 5 feet until it would be WAAAY off, and you'd need a tuner to use it at all. NO fun.

So I have build the Carolina Cyclone for the past 10 years. It is a basic, good-looking screwdriver. It does not use PVC at all. All parts are machined in a professional shop, and these parts are hard, black nylon. It allows one to use an amplifier up to 1000 wattsSSB (1500 with the Cyclone II) without worry. It comes with either a clear or a Sked 20 PVC coil cover (don't confuse with that with the INTERNAL works). Some people actually like the solid cover and it gives the optical illusion of being "shorter" than it actually is--nice for those XYL's/spouses that object to tall antennas. Your choice as to the cover.
And while many screwdrivers cost hundreds more, the Carolina Cyclone costs only $240--$350 for the Cyclone II. Shipping is included in the price, but price is also less whip(they are too darn hard to package and ship). And if you are running an Icom 706, I will include a little module that will allow you to semi-automatically set your antenna quickly with a tone signal.

I don't do a whole lot of advertising, and I am retired so this gives me a little work in my shop. I love building antennas and this gives vent to my hobby,

Hi Jim,

In fact it is explainable (done it several times here in fact) and is
called mismatch uncertainty which is quantifiable error derived from
attempting to measure power between two mismatches. When the
generator mismatches the line by as little as 2:1 and so does the
load, you are already pushing 20% error.

However, the quantification is resolved through interference math.
No, not like the stuff presented in this "Can you solve this," but
close enough (sans the howling errors of commission).

>And isn't it true that if there were actually a real hard short or a

I am now the proud owner of a 8m collapsable carbon fiber roach fishing pole.

I live on the 9th floor the (top floor) of an appartment block. I have a hemi-eliptical balcony, about 3-4 meters across, I have a steel balcony railing streching around enclosing it. There is a steel drain dipe running through one corner of the balcony. I have unlimited height (blue sky). I thought of lashing (or using sterling hose clips) to secure the first section of the roach pole to the one corner of the balcony, then I thought of using the top of the fishing rod to suspend one end of a trapped dipole or G5RV(?) antenna, and fixing the other via an insulator to an eye hook in the wall...

Only problem is the pole might be struggling to support the weight of the trapped dipole.....(?)

With the above features, what would be the optimum 10, 20 and 40m solution given the space I have, roach pole (supports limited weight), drain pipe (good ground??), balcony etc...

Either commercial or homebrew, prefer home brew....

Tim

Larry, the Zepp was *never* designed to match 50 ohms. It was
designed to be used with tube final rigs which contained
built-in antenna tuners of one sort or another. Moral: A Zepp,
when used with 50 ohm transmitter, is going to require an
antenna tuner unless you are extremely lucky on one frequency.

Source record: 73204

At the OKC hamfest I got a piece of neat looking coax that is double
shielded with silver braid, with a sort of clear pink outer cover. It has
connectors so I don't know the thickness of the center conductor.
It's stamped with the following characters:
68999, AA-2831. 81205, 204-15578-1, AUGUST 1996

I asked the seller, an ex-Boeing employee about it and he said it's the same
kind as used in Air Force One. He couldn't recall the specs but said it was
Teflon, good to a Gig but he had used it outdoors. for 2 meters and 440.

Can anyone tell me more or point me to a site?
tnx
--

73
Hank WD5JFR

I've tried to find the specs but get only one hit googling::
http://www.waea.org/tech/techdocs/SatSpec0798V1.doc

This site kind of confirms what the seller said.

Who said it is baffling? The problem is that if you cannot understand
the simplest of examples involving lossless, refractionless, laser
systems, you cannot possibly understand anything more complicated.
I haven't even read past your inability to understand that simple
example.

Yep, which is exactly what happens with W7EL's "Food For Thought #1".
The fact that Roy didn't choose to mention the 2.828 amps of current
flowing in the middle that 1/2WL of transmission line is interesting.

To that list of two, we can add two more. If the source end of a
transmission line is terminated in a pure reactance, it re-reflects
the reflected wave.

When 100% wave cancellation of reflected waves occurs at the source
due to total destructive interference, it re-reflects the reflected
wave energy components as constructive interference energy in the
opposite direction. Anything else would violate the conservation
of energy principle.

Hmmm. I can't say "optimum" but I think you'd be able to get some
very usable performance out of a system in which you use the balcony
railing as a support and ground/counterpoise, mount a support and
insulator of some sort at one end of the railing which holds the
fishing pole outwards at an angle of about 45 degrees, run a wire up
the pole as your radiating element, and use some sort of
tuner/matching system at the support/insulator point to tune the
system.

8 meters of wire as a radiator is more than you need for a
quarter-wave on 20 meters - you'd actually get a bit of gain out of
it. It's not quite 1/4 wave on 40 meters, but it's probably close
enough that a halfway decent tuner (or the addition of a small loading
coil) at the base could give you a good match on 40 meters as well.

Hooking up the railing to the drain pipe (if not already connected)
might increase the efficiency of the ground/counterpoise system.

However, it might also increase the risk of RF going where you don't want it, and creating shock, burn, or TVI risks for other residents of your building. There can also be problems where drainpipe segments meet... if the junction is corroded or is just force-fitted together, the metal-to-metal junction can act as a rectifier and create lots of harmonics and other RF nasties.

Take a look at The St. Louis Vertical QRP antenna project:
http://www.amqrp.org/projects/stluisvert/STLV%20Project.html

There are thousands of unterminated wall outlets and hundreds of
terminated wall outlets spaced only a fraction of a wavelength from
each other. By all means, if you cannot understand the simplest of
examples, create an example that is so complicated that nobody can
understand. This is an example of someone trying to obfuscate things
in order to reduce everyone down to his/her low level of understanding.

> Noting of course that EM energy can't normally put itself back into the
> source after it's done bouncing around. So, since there's no load and

> means zero power.

Zero *NET* power has nothing to do with the component powers. All it means
is that the forward power and reflected power are equal. The losses in
a real world transmission line depend upon the magnitude of the forward
and reflected powers which pretty much shoots your illogical argument in
the foot.

The higher the voltage applied to a real-world 1/2WL transmission line,
the greater the losses absorbed by the feedline. How the heck do you
explain that one by neglecting forward and reflected energy?

In other words a system in which all of the power from the source
reaches the load and none is reflected back to the source without first
reflecting then re-reflecting would violate conservation of energy.

It's like saying a ball violates conservation of energy if it rolls down
hill without first passing through a Rube Goldberg contraption.

jeez, ac6xg

Jim Kelley wrote:
> Interesting to note that the interference phenomenon is often described
> as a redistribution, but is never described in any reference as a
> reflection, or re-reflection as you have done.

That's easy to understand in the context of light which can take a
vector in any direction in 3D space. However, a transmission line
is essentially an one-dimensional world. If something happens and
it doesn't happen in one direction, there is only one other direction
available. In other words, a redistribution of energy in a transmission
line is, by definition, a reflection (or re-reflection). If things
continue on in the original direction, it is not a redistribution. If it
is a redistribution, it must change direction by 180 degrees. That's so
simple a concept even you should be able to understand :-) but you
obviously haven't admitted such so far.

> It doesn't, contrary to your assertion, first go in
> the reflected direction, say oooops, then turn around in mid-air and go
> in the other direction.

I never said it did, Jim. That is at worst a straw man on your
part or at least an extreme lack of understanding of what I said.
Because of your semantic objection, I changed interference events
from happening on either side of the match point to happening *AT*
the dimisionless match point in my article. In my article, everything
happens *AT* the match point, NOT on either side of the match point.

> The reflection is prevented. Comprende senor?

Yes, I agree 100% and always have. The reflection is prevented by
wave cancellation of two reflected waves. We have been over this
item a hundred times and you still think your straw men will work?
Instead of introducing every diversion known to man, why don't you
just discuss the technical details? We agree 100% except for the most
minute of details and you have been aware of that for months now. You
have even said that in private emails to me.

> The Bird wattmeter can be misleading in this regard. It measures the
> effect of a field (sometimes like the one in Born and Wolf that doesn't
> have transfer of energy associated with it), and in every case assumes
> energy and power. But it's simple minded so it has an excuse.

It certainly depends on your definition of power. Yours is not the same
as the IEEE Dictionary so you have an excuse. That excuse is obviously:
"Physicists are superior to engineers in every way and are allowed special
sacred cow privileges when defining words!" :-) Engineering power does NOT

require that it be dissipated, it only requires that energy be flowing.
Joules/Sec flowing past a point satisfies the definition of power as
defined by the IEEE. The Bird Wattmeter measures IEEE power.

Everything I said is 100% consistant with the laws of physics.
Your "in other words" statements violate the laws of physics.
Every "in other words" statement that you have ever made, Jim,
has been 100% incorrect. Maybe you should try to understand
the concept before offering an "in other words" statement?

"Physical damage is generally caused by direct strikes."

Lightning can produce awsome distruction from its millions of volts and thousands of amps. Stories about it are informative, amusing, and abundant.

Damage is mostly avoidable. High towers are nearly certain to be struck repeatedly in passing thunderstotms. I`ve worked in medium wave broadcasting, Short wave broadcasting, land-mobile radio, aircraft radio, and microwave relay systems aplenty. I worked decades with a worldwide corporation that had towers across the U.S.A. and several other countries in the world. That corporation had its many towers fitted with inverted Copperweld ground rods at the top to serve as lightning rods to take most of the hits the towers received. At their bottoms, the towers` lightning energy was shunted off to the earth through ground rods driven into the soil around the towers. It worked. There was no vaporized coax, tower lighting wires, or anything else.

We had to operate perpetually. We couldn`t pull the switch and throw the coax out the window, even if someone were on hand to do so.

Evidence of lightnong strikes were the small pits it made in the lightning rods.

Best regards, Richard Harrison, KB5WZI

Rick the original has limited power handling capability, a small diameter coil and no posititioning circuitry or automatic control. Compare it for example with the offering from http://thescrewdriver.com Compare the specs of some of the offerings of other vendors as well.

While I agree that some out there are junk, a number have made improvements in construction, control, and power handling capabilities.

Or you can do as I have done and build your own. Assuming you have a friend that has a lathe to cut the grooves in your core material, your willing to rework a screwdriver motor, find a couple of friends to build one with you, it can be built for about $70.00.
.
If you do it by yourself, be prepared to buy a 12 foot length of copper vent pipe and not use 8 feet of it. Minimum orders for phospher bronze finger stock, and a minimum of 12 mailing tubes and covers of which you will use one of each. Then you are talking about $130.00 for materials not counting the PVC, matching coil, control box, capacitors, and mounting hardware.

Had I not been involved with a bunch of great guys over by North Augusta, I doubt I would have built one myself.

Hi Rick,

Why so argumentative?

As far as I'm concerned, the more good ol' boys we have making
different antennas, the more choices we'll have. Do you think
choice is a bad thing? If someone else's antenna offers better
value than the poster (in your opinion), then buy someone else's
antenna. That's how the free market works. 8-)

Maybe you should ask Rummy why he's paying $100,000+ for Hummers when
the Original, the Jeep, runs about $16,000.

Hi Squeege,

Check out the Sony AN-LP1. It works very well, and I don't
think you can beat it at the size. It's particularly nice with
Sony's budget HF receiver, the ICF-SW7600GR. Just stick
the suction cup on your apartment window, and you're in
business.

I understand the concept, but if I have a wire antena , going to ladder line, the trasitioning to coax, all outside, with the coax finally snaking into the house and hooking up to the antenna tuner...

Where would I put grounds, how would I attach them, etc...???

I'm having trouble visualizing doing this grounding without it affecting the antena performance.

Jerry

(who was generalizing when talking about house damage, but was really just looking for help with ideas for grounding and thank you all who have responded)

Perhaps, to do it justice, I should explain that my one and only
experience with a Zepp antenna was in a situation in which the 1/4
wave balanced line section was open wire feeders with about 6" spacing
and the transmitter used a pair of plate modulated, push pull 10's as
the final - link coupled, as I already mentioned. In those days no one
had a clue as to load impedances or conjugate matching. We had an RF
ammeter in the transmission line and we tuned everything for maximum
reading on that meter. Those were the days.

Fred W4JLE wrote:
Not to "knock" the name brands in HF mobile, but have you ever wondered
why
they cost so much--up to 700 bucks for a screwdriver all-band mobile
antenna? I do because I couln't AFFORD to pay 5-7 hundred bucks for
a mobile HF antenna! And it's not the performance you are paying for; it's
fancy paint jobs and "consumer" gimmickry that run the price up

This was your original ... Im not Knocking yours. I only POSTED exactly
what you did yet you took exception. WHY?

I cannot afford 5-7 for those nor can I pay 250-350.

But 175 is more reasonable

Why do you Knock MY choice when your advertising YOUR choice. I was
mearly Pointing out

> Or you could pay 175 for the Original made by the original Designer.
> Why should it be 240-350 when 175 will do ?

I pointed out you could pay 175 instead of 240-350. Then you go on
in your second to tell me I should go and build one myself go buy the
stock and YADA YADA. WHY, what does that serve to tell me. Im shopping,
Do you as a sales person who actually is comparing prices for products
tell me to go build my own. Would a car dealer ???

I dont see why your so defensive. If you have a good product people
will buy it. Some wont, but to tell me IM wrong for comparing is wrong.

I run 100 watts, always have always will, so what does it do for me to
have these bigger coils etc. Hell I run Iron Horse whips and can run
with a lot of screwdrivers because of the way I install and run them.
Many swear Im running a Screwdriver already. So what.

Im looking for a single antenna that does what a screwdriver does.

You posted, I posted an alternate and now your up in arms.

How about if I get all the other MFGs in here to get all up in arms with
your posting because your saying they are too costly.

>If you have dared to peak inside a magic circle box please tell

I have a Cushcraft R-7, which I got by trading in an R-7000 (long
story). It has a black box about 8" x 6" x 2" that is the matching
network, etc., into which the 50 ohm coax from the transceiver plugs.
I opened it up once and had a good look around. I closed it back up
and have never given it another thought.

Jim Kelley wrote:
"In other words a system in which all of the power from the source reaches the load and none is reflected back to the source without first reflecting then re-reflecting would violate conservation of energy."

Conservation of energy means that energy is neither created nor destroyed, but that heat and other forms of energy are quantitifiable and convertable in their equivalence. The total amount of mechanical, thermal, chemical, electrical, and other forms of energy in any isolated system remains constant. A century ago, Einstein broadened the law to include equivalence of mass and energy.

Regardless of reflections and re-reflections, all the energy sourced into a transmission line ends up in the load if it isn`t lost in transmission by radiation or conversion into heat. There`s no place else for it to go.

Best regards, Richard Harrison, KB5WZI

There is no problem matching up a zep for a modern transciever.
Think of it as a J-pole with the long end bent over horizontally.
Short the bottom of the quarter wavelength section, and find a point
above that to match to 50 Ohms as seen on an antenna analyzer or bridge.

Should be easy.

Source record: 73090

Jerry wrote:
"I`m having trouble visualizing doing this grounding without affecting antenna performance."

Shortwave radio antennas I`ve used were all made from Copperweld wire to withstand lightning and weather. Also, copper wire can stretch and fatigue. Copperweld`s steel core prevents this.

Signal Corps rhombic kits use (3) No.12 Copperweld wires twisted together to make a cable used for antenna and transmission line. A special Wihd Turbine Company insulator is included to space the line for 600-ohm impedance. These bolt atop short tower secttons used as transmission line supports. Unless military surplus is available, substitutions would be necessary. But, open-wire line is rugged and withstands the challenges.

Pick a place outside your shack to drive ground rods to serve as a ground bed for your antenna system to dump your lightning strikes to. Place the rods at about the length of your ground rods away from each other. The more rods, the better. Cost will prevent too many rods.

Interconnect all the ground rods and connect this ground system to your electric service ground system. It`s the law in most jurisdictions.

Run your open-wire line from your antenna to a point above your ground bed. You need arc-gaps between each transmission line cable and the earth. Form copper vees to make arc-gaps. The vertex of one Vee is going to face another to make a pair. Connect one Vee firectly to the earth. Connect the other of the pair directly to the transmission line cable. Do the sane for the other transmission line cable.

When the gaps are completed, adjust the space between them until they flash over from your transmitter power, then back off until they just don`t flash over. You should now be ready for lightning on the transmission line. Connect your ladder line, twin lead, coax or whatever you will use to complete the connection to your radio to your open-wire line here above your ground bed.

Isolate the radio from the powerline through a brute-force filter with MOV`s added for lightning suppression.

Audio, control, and any other wires connected to the radio also need filters with MOV`s added but the current carrying capacity of the filters can be lower than that required for the power wires in most cases. A common ground point is required for all these filters.

If you don`t use coax somewhere between your radio and antenna, you will lose some of the protection it provides. Its close internal spacing couples its conductors tightly. We found even solid-state receiver front-ends weren`t endangered by lightning because of grounded antennas and the coax. It would flash over before it let lightning through.

Best regards, Richard Harrison, KB5WZI

It doesn't. All reflections are eliminated by wave cancellation.
That is a given boundary condition for the simple example.

You can argue that there's no such thing in reality as a
dimensionless point or a line of only one dimension or a
plane of only two dimensions. That doesn't keep such from
being taught as concepts in every plane geometry class.

What a larf. :-)

If you can't explain it, you simply re-write the math to suit the
outcome? This is neither demonstrable nor provable, unless, of course
you simply fudge the numbers until they agree with your result. Given
that every reader here has had the opposite experience as your
prediction, this is classic thumb on the scale work - quite shabby.

It seems you have forgotten the purpose of the laser example.
It was supposed to be as much like a transmission line example
as is possible. Refraction is irrelevant in a transmission line
so there's no logical reason to introduce refraction into the
simple laser example. A laser was chosen to make the example
single frequency and coherent like an RF source. Occam's Razor
is used to trim off all irrelevant stuff.

No one is forcing you to explain what you cannot. What you choose to
respond to is strictly your choice and wholly your responsibility. If
you don't care to answer for why the reflections of your model are
TEN TIMES BRIGHTER THAN THE SUN, and call this power cancellation
instead, no one really expects you to anyway.

Why don't you give us another hymn instead about understanding and
such? Is your paper in the hands of a devotional publication? Do
they cater to a herd of sacred cows? Would this make you a holy
cowboy? :-)

The purpose of the laser example is to make it as much like a
transmission line example as possible. A Bird wattmeter indicates
that all reflections are eliminated in the T-line example so
the laser example assumes that as a boundary condition. Your
insistance on rewriting the math to make it as different from a
T-line example as possible is simply a diversion away from the
original purpose.

I have been reminding you of "Glare" and asking for its wavelength for
months. No, I have not forgotten, I just haven't gotten an answer is
all. Let's face it, when your xerox crutch didn't include that
detail, your dearth of experience drew a blank.

If you want, I can answer it for you - just like all the other power
questions that attended your "laser design." You see, the difference
is that I've worked with and engineered them instead of building
flip-flops (do I note a similarity in your writing style here too?).

It takes more than simply being the holy cowboy of the sacred herd.

Never met the class of Bird wattmeter that measures laser - and
neither have you. Get your thumb off the scale and put it where it
belongs.

Already answered. A Bird wattmeter indicates zero reflections
in the T-line example so *ZERO* reflections are assumed as a
boundary condition in the laser example. The net reflections
are NOT ten times brighter than the sun - they are flat black,
by definition.

I assume you know how to calculate the wavelength of a
single-frequency coherent source like the one assumed
in the laser example. WL=c/f

Hi,

IMHO there is no miracle to work in such solution. I have the same problem, having moved in a modern appartment where I am not allowed to erect any antenna on the roof. So remain the portable solution.

In your case, for reception, why not to test an active magnetic loop antenna. They cover all the spectrum in continue
see e.g. http://www.astrosurf.org/lombry/qsl-ala1530.htm

As you are licensed I think, there are also magnetic loops for TX, see e.g. www.wimo.de
Only drawback, better to stay over 7m from the antenna due to the magnetic field generated. If you can do that, it's fine. Its performances are not better than a dipole but its is somewhat directive. That helps.

Hope this helps.

The boxes contain tuners for small loop antennas. Go to the mfj site;
they show an internal picture of the 933 loop tuner. Couple of
variable caps. You might also see if you can download the manuals for
these tuners from the MFJ site -- many are available.

Or check your ARRL Antenna book for tuning circuits for small loop
antennas. No mystery.

Source record: 73106

Henry:
From: http://www.nrcdxas.org/articles/coax.html

The recent popularity of a new antenna cable called Skyhighgain Coax has created a safety problem for users and a nightmare for firefighters. SHGC was developed theoretically by Tricenters Experimental Laboratories, Inc. as a signal-boosting element for use in radio and television transmission lines. Scientists at TELI discovered that when a bias voltage is applied to the special material used to make SHGC the effect was incredible. Instead of simply reducing signal loss, the signal strength increased!

Amplification of RF (radio-frequency) signals in the new coaxial transmission cable was actually greater than 3 db (decibels) per meter per meter. (Read that again.)

In laymen's terms, that means that for every 10 centimeters a signal travels through the cable the signal strength doubles! Put 1 Watt of RF energy into one end of a one meter length of SHGC and you get 2 Watts at the other end (assuming you supply the bias voltage, of course). At two meters you get 4 Watts. At three meters the signal strength increases to eight Watts. Doubling the power every meter the total effective power of the signal exceeds 1,000 Watts by the time it has traveled only 10 meters up the line.

Now imagine what would happen if you had a 100-meter SHGC cable. (The actual figures are shown at the end of this article.)

In conventional transmission lines there is always some loss of signal depending upon frequency and the electric characterists of the cable. But with SHGC, instead of a loss, you get a gain in signal strength. This is the stuff every radio engineer has dreamed of.

But here's the problem. The unwary (and mathematically challanged) average user seems to think that if a short section of SHGC inserted in his transmission line is good, then a longer one is better. If one were to, say substitute SHGC for the complete run from their radio shack to the top of their tower, the signal would have more energy than the cable (or the antenna) could withstand. (The 20-meter traps on the tri-band beam that used to be on the 60-meter Rohn 25g tower behind the house in the photograph above were never found.)

Designed to be used in short sections between standard coax and the antenna, SHGC is not currently available, pending the resolution of certain limiting manufacturing capabilities. Some reports have surfaced however that a few samples of the hot-pink colored coax have somehow slipped past reality checkpoints and made their way into the Amateur (and amateur) community. And without official spec sheets and installation guides SHGC poses a

significant hazard to the uneducated.

The following table dramatically illustrates the danger of using too much Skyhighgain Coax in any transmission line.

Length of Coax / Power Output

1 meters - 2 Watts
2 meters - 4 Watts
3 meters - 8 Watts
4 meters - 16 Watts
5 meters - 32 Watts
6 meters - 64 Watts
7 meters - 128 Watts
8 meters - 256 Watts
9 meters - 512 Watts
10 meters - 1,024 Watts
11 meters - 2,048 Watts
12 meters - 4,096 Watts
13 meters - 8,192 Watts
14 meters - 16,384 Watts
15 meters - 32,768 Watts
16 meters - 65,536 Watts
17 meters - 131,072 Watts
18 meters - 262,144 Watts
19 meters - 524,288 Watts
20 meters - 1,048,576 Watts
21 meters - 2,097,152 Watts
22 meters - 4,194,304 Watts
23 meters - 8,388,608 Watts
24 meters - 16,777,216 Watts
25 meters - 33,554,432 Watts
As you can see, by the time you reach only 20 meters, the signal power has exceeded a million Watts! Assuming your facility's commercial power mains could handle the load, the signal would exceed 30 million Watts at only 25 meters from the transmitter.

Of course, most power main breakers would trip long before the million Watt level, but once the signal starts up the transmission line the peak envelope power (PEP) climbs so fast that there is a possibility that the circuit breakers would either fuse or the electric current would simply jump the breaker's open switch gap and power would continue to increase until the primary main lines evaporated in what could only be described as an artificial bolt of lightning, showering every surrounding structure in hot plasma and sparks.

LEGAL WARNING: positive gain coax was patented in the late 1980s by the muTek company in Britain, under the brand name "Gainiax".

Following established precedent in this newsgroup, unauthorized users of this patented technology will be pursued with the full vigour of the law.

muTek advertised this new product in an April RadCom... and received several serious inquiries.

Unfortunately the factory did not survive the first production run. The last words heard over the phone were "You want the ends of these reels shorted together?"

Good enough for what?

Simplified concepts are sometimes good enough for simplified purposes. But all too often, people try to extend them to phenomena which are beyond the range of the simplified concept's validity. So you end up coming to conclusions which are absurd at best and subtly wrong at worst. (I say absurd at best because hopefully they'll at least be obviously wrong, while the errors in subtly wrong conclusions are not so apparent.)

But if I'm properly interpreting your quotation marks as meaning that the enclosed terms are vague or poorly defined or that you don't have a complete grasp of their meaning, your working concept includes at least nine terms which are in this category. As such, I doubt that it's a good working "hallucination" for any use.

The language of science and engineering is mathematics. Without the ability to use mathematics to describe physical and electrical phenomena, any "working" explanation will fail at some point. The problem is that it's often not apparent just where this point is.

3003. Why you can't solve this 2(bad)

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-19 16:40:39 UTC
From: Richard Clark <kb7qhc@comcast.net>
Message-ID: <ej8qd1dfu5u3v1omk36qs3dieqvq8is2la@4ax.com>
Source record: 73117

Thus has it been told by the Holy Cowboy of the Sacred Blind Longhorn:

>Reflected energy is eliminated at the air to thin-film interface
>because of wave cancellation (total destructive interference).

This Sermon given somewhere in the Sepulcher of the Prairie was to
remind us how similar this parable was to transmission line
experience:

> The example I gave was designed for clarity of understanding.

It was further given that all revelations were proven through the
witness of the Holy spirit of the Range:

>A Bird wattmeter indicates that all reflections are eliminated in the T-line example
>so the laser example assumes that as a boundary condition.

The Bird has a stated inaccuracy of 3% (neglecting all other sources
of error) and the example above exhibits 1% products. As such, the
testimony of that Holy spirit of the Range reveals that either the
math offered is in error, or the theory is error, or the assumption
(same thing as theory in this case) is in error.

Hence the contradiction explicit within this testimony. The Bird does
not indicate any reflections - or rather it indicates erroneous
reflections (as both are equal outcomes when the inherent inaccuracy
exceeds the products by 3:1).

However, when this testimony was offered, the voice from the
Smoldering Tumbleweed imposed:
>All reflections are eliminated by wave cancellation.
>That is a given boundary condition for the simple example.

Hence we have the Miracle of the Holy spirit of the Range's
infallibility. That Miracle is that even sitting on the shelf, the
Bird's off zero indication is a revelation of reflections in the
ï¿½ther.

To give proof to faith, we have the Miracle of
>The incident intensity upon the 3rd medium is 1.0101w.
wherein with each splitting of the wave feeds the multitudes.

>Your insistance on rewriting the math to make it as different from a
>T-line example as possible is simply a diversion away from the
>original purpose.

The Divine Purpose, using the Holy Cowboy's Sacred Text, has been
impugned by the Sacred Cowboy to prove the Divine Purpose. It is a

heresy for those not in the Order of the Sacred Blind Longhorn to
employ this Kabala of numerology which is the right of Priests alone.

The Smoldering Tumbleweed once again pronounces:
>The net reflections are not TEN TIMES BRIGHTER THAN THE SUN -
>they are flat black, by definition.

And I said -
Let there be light!

Am putting a 10 meter mono on top of a 4 element tri-bander. There
will be about 8 ' separation. First, will I have a problem with the
10 meter beam interacting with the 10 meter portion of the tri-bander?
Second, what kind of interaction would I have if I put a short two
meter beam between the two. I am restricted to one tower, but I hate
to give up the performance of the 10 meter mone for the next cycle.

Thanks for your reply Bob but it is the 935 or 936 loop tuner that I am
interested in and not the 933.
the one that converts a short piece of wire into a small tuned loop.
Cheers

There is no reason anyone living in an apartment can't get on the air, at least to some extent. Have you checked MFJ products for antennas that would suit your needs? http://www.mfjenterprises.com

There is the mini whip apartment antenna for 40 - 10M, which will mount right on an outside window sill, MFJ-1622, and there are a number of totally indoor antenna loops you can use, although they are rather pricey, such as MFJ-1788. If you operate QRP at 5 watts, or even up to around 20 watts, none of your neighbors will even know you are on the air. Good luck

Ed

Didn't you even look? On their website there is a beautiful high
resolution picture of the interior of the MFJ-936B tuner. I would hazzard
a guess that it is nearly identical to the out-of-production 936.

Thanks I have just located the page and the pictures are very good.

Cheers and thank you all for your help.

3010. Exotic coax ?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-19 18:18:18 UTC
From: Henry Kolesnik <kolesnik@sbcglobal.net>

Source record: 73125

If you don't suceed try again. Sorry for the repost but my previous post drew nothing useful. Is this site getting like the rest of the Internet?

At the OKC hamfest I got a piece of neat looking coax that is double shielded with silver braid, with a sort of clear pink outer sheat. It has connectors so I don't know the thickness of the center conductor but the seller said it was 50 ohm.
It's stamped with the following characters:
68999, AA-2831. 81205, 204-15578-1, AUGUST 1996

I asked the seller, an ex-Boeing employee about it and he said it's the same kind as used in Air Force One. He couldn't recall the specs but said it was Teflon, good to a Gig but he had used it outdoors. for 2 meters and 440.

Can anyone tell me more or point me to a site?
tnx

It could be, although I dont remember it specifically when I installed
coax on AF1 (1990). But that is Equivilant to Boeings BMS13-65.
Which is Coax for Satcoms.

It seems to. Since he wrote "all the energy sourced
into a transmission line", it's doubtful that he was implying that any
heat energy was sourced into the transmission line. That would be silly
(RF transmission line is opaque in the infrared). He probably also
assumed that the energy dissipated by the front panel lights wasn't
sourced into the transmission line either. You forgot to ask about
that. ;-)

You missed the implication which was: Does any RF energy
exit the source only to re-enter the source again later
and wind up being dissipated as heat? For instance, we
know that a capacitive load is capable of returning
energy to the source during part of the cycle.

That implication did escape notice. Clearly Richard was talking about
something else.

But it's an interesting question. It would be nice to see some
objective data.

Try a Google search for 204-15578-1. I got one hit. Also look for
68999 in the pdf file at
http://www.timesmicrowave.com/content/pdf/tl14/28.pdf, and do a Google
search on '68999 coax'. Things like that might get you somewhere...or
might be dead ends.

Also, measure the impedance. The size will give you a good indication
of the loss, or just measure it.

Cheers,
Tom

Jim Kelley wrote:
"You take too great a liberty with the name Eugene Hecht. Among the things which won`t be found in any of Dr. Hecht`s texts is a minus sign in front of a number expressing an impedance."

Don`t know why not. It happens at radio frequencies all the time. Look through Kraus` chapter on "Mutual Impedance of Other Configurations".

B. Whitfield Griffith, Jr. gives a practical example starting on page 427 of "Radio-Electronic Transmission Fundamentals". On page 429 he writes:
"We immediately notice one disturbing fact: the resistance component of tower 1 has come out to be a negative number. This does not mean the computations are wrong; it simply means that this tower because of the particular phasing and current relationships of this array, will be absorbing more power than it will be radiating itself."

This is an old story with broadcast antenna arrays.

Best regards, Richard Harrison, KB5WZI

Hmmm. I wonder whether this might not be Times Microwave 68999, a
mil-spec hermetically sealed .34" coax. Silver-plated copper-clad
aluminum center conductor, taped PFTE (Teflon) dielectric, triple
shield (silver-plated copper strip, aluminum-backed tape,
silver-plated copper braid), FEP (Teflon) inner jacket, Nomex outer
jacket. 50 ohms, rated to 18 GHz.

Definitely exotic stuff, intended for applications where long-term
reliability is extremely important.

Yes, thanks Richard. It is quite a simple concept. But my contention really isn't about conservation of energy. It's about the 2nd law of thermodynamics. Nature does not require a rolling ball to run through a Rube Goldberg contraption in order to conserve energy. In fact it generally abhors such things. "One should not increase, beyond what is necessary, the number of entities required to explain anything."

Cecil Moore, W5DXP is alleged to have written:
"Nor will we find a negative scalar quantity accompanied by the claim that the negative sign indicates a change in direction as you have done."

Have not read Hscht, but I`ve read Terman and realize that a transmission line can guide a wave only forward and backward. Sometimes backward is considered the negative direction.

Terman gives an example on page 90 of his 1955 edition:
"When the load end of the line is shorted, that is Eload =0 , reference to Eq. (4-14) shows the reflection coefficient has the value -1.0 on an angle of 0-deg.= 1.0 on an angle of 180-deg. As in the open-circuited case, the reflected wave has an amplitude equal to the amplitude of the incident wave. However, the refleection now takes place with a reversal in phase of the voltage and without change in phase of the current."

The firm has been sold on twice since the Good Old Days.

Meanwhile its first - and last - production batch of Gainiax (TM) is
still melting its way down towards the centre of the Earth.

I'd go to the Wireman's web site, and just call them on the phone.
They seem to know everything there is to know about coax.

Yes, for vector quantities expressed as a function of position or time.

> Terman gives an example on page 90 of his 1955 edition:
> "When the load end of the line is shorted, that is Eload =0 , reference

From Webster's Collegiate:
Scalar - a quantity such as mass or time that has a magnitude
describable by a real number and no direction

Power as a scalar quantity does not have direction, and so one could not
for example subtract power 'moving' in one direction from power 'moving'
in the other direction by arbitrarily multiplying one of the magnitudes
by negative one.

All you need is a length of plastic-insulated wire strung up in the
attic, or unobtrusively tossed out of a window, and a large aligator
clip attached to the domestic plunbing system. Plus a simple tuner.
Believe me - it really does work very well! Ask any real amateur.
And don't get yourself all mixed up about so-called SWR, reflected
power and take-off angles.

Hank, try also googling <68999 coax> and you'll get a little more. Is there nothing you can identify as a manufacturer's name or logo?

You should be able to estimate the loss pretty accurately from the size, and you should be able to measure the impedance with enough accuracy for amateur use pretty easily. Resonance and physical length will tell you the propagation velocity, if you need that.

I'd guess it to be Teflon-insulated and Teflon-jacketed. Does it matter a whole lot for what you want to do with it?

Cheers,
Tom

By the same token, why would you buy an Escalade when a Ford will do? The difference is materials and the ability to run power if desired. PVC is not really a good form for loading coils. Phenolic is messy and much more expensive. The original uses #16 wire wound at 10 TPI; I prefer #14 at 8 TPI which is actually more efficient. You can even to to #12 at 6 TPI. Not sure that isn't past any real gains in efficiency, tho.

Yep, that's what I told him. In fact, Ramo & Whinnery illustrate
the Poynting vector for forward power as Pz+ and the Poynting
vector for reflected power as Pz-. The net power is (Pz+)-(Pz-).

For engineers, the direction of the arrow for the Power
Flow Vector in joules/sec is generally accepted to be the
same as the direction of the joules.

From the IEEE Dictionary: "power-flow vector - Vector-
characterizing energy propagation caused by a wave and
giving magnitude and direction of power per unit-area
propagating in the wave."

Please note the "*DIRECTION OF POWER* ... *PROPAGATING*
in the wave", a direct contradiction to your above assertion.
The power measured at the source somehow finds its way to the
load in spite of not having any direction (according to you. :-)

Most of your rantings and ravings over what I have said
are simply semantics and definitions. RF energy and RF
power are so closely related that Walter C. Johnson talks
about the "principle of conservation of power".

Terman did so rather deftly. We make simplifying assumptions and replace the general case with the special case all the time. Bird defines true power delivered by the source to the load as the difference between its forward and reverse power indications. It`s satisfactory in most cases.

Inductive and capacitive reactances are routinely added together to give the net reactance and it works fine so long as the reactances are pure. They lie on the same axis but in opposite directions so can be treated as scalars. Another special case.

Hi Richard,

That's because the vector arrow is printed on the knob. You won't find a vector notation in the math that has been bandied about because it deals with Scalars and Phase independently (and absolutely no direction expressed whatever).

Any introduction of direction is purely an invention unsupported by references so far expressed. However having pointed this out, like the multitude of mistakes that have gone before it, is not going to change the pantomime.

Marcel can go through the motions of wiping the window clean, but there's no glass there. ;-)

Lightning attaching to a wire will instantly vaporize the wire.

Not always. Depends on the resistance of the
ground connection. If the resistance is low, a # 6 wire
can take a direct strike, and barely warm up at all.
Even a #10 is ok, if the connection to ground is good.
You might see a tiny pit where the point of contact
was. But a high resistance ground connection, and
yes, it will fry. I've taken two direct strikes on my mast,
and can see no damage at all. You can see a tiny pit
where the strike connected to the mast top, but even
it could be easily missed. According to my experience,
I think the quality of the ground connection also effects
the sound of the strike, not counting the sonic boom overhead.
A strike hitting my mast is very quiet. It's like a light bulb
being thrown on the ground, "plink", and you hear the overhead
sonic boom. But when it hits the trees with their high resistance
to ground, the strike is earsplitting. "CRACK-BAAAAAMMMM".
:(Thats the "local" sound, not the sonic boom, although they mix.
I don't operate during storms, and doubt I would, even if I could.
I unplug the antennas, and ground them out to ground outside
the window. If I *had* to operate during a storm, I would use my
attic dipole. It's the least likely to take a hit, in general.

The reason Varney used a G5RV in preference to an ordinary dipole was because of its clover-leaf radiation pattern on 20 metres. He is quite clear about this. He could work Europe and N.America from S.America without changing antennas. Otherwise, for 20 metres, he would have chosen the better antenna - an ordinary halfwave dipole which also can be used multiband over an openwire line, the line being conveniently of any length.

The reason the G5RV became popular with amateurs was because of its theoretical attraction when Varney published it. The ideas of cloverleaf and 1/2-wavelength feedline, combined in one simple system, were quite clever, easy to understand and therefore intellectually attractive. Also, 20 metres happens to be the best all-year-round, day and night, DX band.

And so began the bandwagon. With a little forced imagination on the part of dealers, multi-band operation (on which it is weak) soon followed.

Even its name, The Famous G5RV, sounds very nice. If Louis Varney had had a call like BF6POX nobody would ever have heard of it.

You must have missed the IEEE Definition of "power flow vector".
It speaks of "power ... propagating in the wave". Here's another
definition from the IEEE Dictionary:

"power vector - ... a vector whose magnitude is equal to the
apparent power ..." A power vector diagram in three dimensions
appears with this definition along with its direction. There
is a vector for distortion power, reactive power, and active
power, all orthogonal to each other, vectorally adding up to
the total power vector. I'll bet you are rolling Hecht's or
Einstein's eyes again at the concept of "reactive power".

These definitions are conventions from various fields of
engineering. One is not wrong and the other right. They are
simply context based definitions. English is NOT a context
free language. You have your own little sacred cow definitions
from pure physics but please don't try to force them on the rest
of the world. (You would probably say the definition of power in
Chinese is wrong because you can't read it.)

A power company engineer would be confused about your concept of
how the power generated by the generation plant cannot get to the
consumer hundreds of miles away. Ask him what is in his
transmission lines and he will say power, some of it reactive.

Some RF engineers are confused about your concept of how the
power generated by the transmitter cannot get to the antenna.
In fact, if the transmission line is one microsecond long,
the same power measured at the transmitter makes it to the
antenna one microsecond later minus losses. Some incident power
may be rejected by a mismatched load as reflected power, which
is incident upon the source one microsecond later minus losses.

If Varney didn't intend to use the antenna on 80m and 40m, why
didn't he just feed it with coax? 1/2WL of twinlead doesn't change
the feedpoint impedance on 20m but it does wonders on 80m and 40m.

Well, the civilian Humvee started out in the $79M range, and I believe
costs more now. Hard to believe the gov't would get them at 1/3 the
civilian cost. Think I read up-armored Humvees in Iraq are in the
$130M range.

(And I will admit, the Army Jeeps I drove in the 60s were the worst
driving vehicles I ever enountered. Maybe the civilian jobs are more
fun.)

==========

He was averse to feeding a balance antenna over an unbalanced line.
Went against the grain.

Coax was rarely used in his day and age anyway. Too heavy and
expensive.

Everything was open wire. Home made. Couldn't buy it.

Transmitters had tuned tanks and link coupling to openwire line.

And he didn't like RF in the shack. Or radiation from the feedline.
TV's used 45 MHz - the 3rd harmonic of 20 metres.

But most likely, it didn't occur to him.

Reg.

You know some pretty stupid engineers - from the binary field?
P= Iï¿½R
Which one is the vector?
P=Eï¿½/R
Which one is the vector?

Does your power company deliver your 60Hz via laser? Or do they use a
Log Periodic Array? A transmission line like the zip cord to your
lamp? What is the characteristic Z of that transmission line? Is it
matched to the load? To the source?

Sorry to ask all these basic questions so far beyond your ability to
render into TTL. No doubt we will get many explanations but no
answers.

Regarding the G5RV, what is always forgotten, the balanced openwire feedline is halfwavelength long for both balanced and longitudinal modes.

What is the input impedance of the line when in longitudinal mode?

I'll allow you and the other experts to figure out what happens relative to the unbalanced source. ;o)

Reg.

>>(and many users seem to think it can),
>
> Can 250,000 housewives be wrong?
> Of course they can!

Reg, I just modeled the half-sized G5RV using EZNEC.
The dipole is 3/2WL on 10m and the twinlead is 1/2WL
on 10m. EZNEC reports the following 50 ohm SWRs at
the twinlead/coax junction.

10m - 2.0:1, 20m - 2.7:1, 40m - 2.6:11

I would be hard pressed to tell the difference between
the efficiency of a half-sized G5RV vs a resonant
dipole for those three bands.

Typical of you to call someone stupid when they simply
come from a different field and have different conventions
from your personal sacred cow definitions.

> Which one is the vector?

P^ = E^ x H^ (where '^' denotes vectors) The vector
product (cross product) of two vectors is also a vector.
If E^ and H^ are vectors and their vector product is
power, then that power is a vector with magnitude and
direction. (I appologize if that fact bothers physicists.)

> Does your power company deliver your 60Hz via laser?

The wavelength of 60Hz power is about 3000 miles but
it obeys Maxwell's equations just like all other
electromagnetic energy from DC to gamma rays.

I am looking for a folded dipole to be used on shortwave frequencies,
and I have "room" for up to 50 meters (160 ft) lenght.
Does someone know if there is something already built to be purchased?
And where?
With many thanks and kindest regards.
Gio'

On Wed, 20 Jul 2005 11:05:24 -0500, Marcel scrubbing vigorously in the air:

>Typical of you to call someone stupid when they simply
>come from a different field

It stands to reason when that engineer changes the questions to suit the only answers he knows.

Only a stupid engineer would use the cross product to figure out 60Hz transmission line delivery. Really, I too have a library, thick volumes including very detailed specifics of 60Hz power, and they seemed to have built an entire industry without worrying about direction vectors. Luckily they didn't employ flip-flop designers to build linear systems.

>Ask him what is in his
>transmission lines and he will say power, some of it reactive.

The topic of reactive LOADS (not lines) is discussed at great length and nowhere is it stated that transmission lines have power IN THEM. However, your impoverished representation of the power industry knowledge serves only your lame theories.

>> Which one is the vector?
>
>P^ = E^ x H^

The very first formula from the Standard Handbook for Electrical Engineers, Section 11, Power Transmission, Electrical Calculations:
I = P / E (1)
no vector notation used or needed.

> (I appologize if that fact bothers physicists.)
Your guilt has been duly noted.

Standard Handbook for Electrical Engineers, Section 11, Power Transmission, Electrical Calculations, Para 13, Transmission Line calculations:
"Analytical solutions of problems involving vector quantities may be made by resolving each vector into two components - R and jX"
no vector notation used or needed, and certainly direction and power are wholly missing. This is entirely congruent with my statement.

Standard Handbook for Electrical Engineers, Section 11, Power Transmission, Para. 33, Charts and Diagrams:
Figures 19 & 20, Perrine-Baum diagrams.

no direction vectors whatever.

Standard Handbook for Electrical Engineers, Section 11, Power
Transmission, Para. 36, Charts and Diagrams:
Figures 22, Mershon diagrams.
no direction vectors whatever.

Standard Handbook for Electrical Engineers, Section 11, Power
Transmission, Para. 44, General Features of Design:
no direction vectors whatever.

Standard Handbook for Electrical Engineers, Section 11, Power
Transmission, Para. 69, System Disturbances:
no direction vectors whatever.

>The wavelength of 60Hz power is about 3000 miles

Standard Handbook for Electrical Engineers, Section 11, Power
Transmission, Para. 73, A Line whose length is a quarter wave:
L = 183000 / 4f
no direction vectors whatever.

FINALLY! The only explicit direction vector (but still no math vector
actually used):

Standard Handbook for Electrical Engineers, Section 11, Power
Transmission, Para. 102, Calculation of Horizontal Stress; Para. 106,
Example of stress-sag calculation; Para. 111 The Thomas chart for sag;
Para. 129, Flexible Towers ...

Well, that's just about the end of it (this tome is only 2000 pages
long and undoubtedly missed your cross product somewhere among all
this useless information).

>yet another tantalizing, unanswerable question: What wavelength is Glare?

Dear Readers,

In this vein, and from contemporary reports from the NY Times comes:
"It's the old story of the C.E.O. who asks the chief marketing
officer, 'What happens if I take 10 percent out of the marketing
budget?' and the C.M.O. replies, 'I don't know,' so the C.E.O.
says: 'O.K., I'll take 20 percent.' "
...
"Marketers are tracking all kinds of data and they still can't
answer basic questions" about advertising accountability..."

This, of course, returns us to the sage advice offered by me
previously:
"Visually compare glare reductions before you buy anything."
especially when the salesman in boots tells you that you cannot see
reflections TEN TIMES BRIGHTER THAN THE SUN.

Salesman: "Any totally cancelled Glare that you will see is Black."

Turning lemons into lemonade:
"Glare that is TEN TIMES BLACKER THAN THE SUN!"
Let's just hope it doesn't turn up in toothpaste. ;-)

Well, it's true for me and probably for most other people who have a grasp of the subject. It's actually energy which does the moving. Power is just the rate at which energy finds its way there.

It's like this. Let's say you're riding your Harley through town at 50 MPH and somebody pulls out of a side street right in front of you. Does the speed of your motorcycle collide with the car, or does your motorcycle collide with it?

Uhhhhh Richard, engineers who understand Poynting Vectors
are not stupid. Do you understand Poynting Vectors? 60 Hz
transmission lines have an E-field and an H-field. Those
fields are vectors. The cross product of those fields is
the power-flow vector. (I hope your upper lip survives that
fact of engineering physics.) Every power engineer that I have
ever known is capable of discussing "power flow" without batting
an eye. However, being a member of MENSA allows me to understand
both sides of the argument. :-) Are you a member of MENSA?

> However, your impoverished representation of the power industry
> knowledge serves only your lame theories.

It appears that what is impoverished is your understanding of
the power industry (and many other industries).

>>P^ = E^ x H^
>
> The very first formula from the Standard Handbook for Electrical

The very first formula in my "Electronics Equations Handbook"
is R = pl/a. The importance of being first escapes me. Are we
to accept the first and reject the rest?

> Engineers, Section 11, Power Transmission, Electrical Calculations:
> I = P / E (1)
> no vector notation used or needed.

Mr. Poynting is rolling his eyes at you. :-) I have heard that
same argument before. "I understand Ohm's Law! Everything else
is gobbledegook!" (Never mind that the poster cannot even spell
"gobbledygook" correctly.)

> This is entirely congruent with my statement.

Which is more important? - congruence or relevance?
(a rhetorical question - no answer required)

> no direction vectors whatever.

You left out: there's no direction vectors in "Alice In
Wonderland". (No doubt your favorite technical reference.)

On the contrary, Jim, it measures and displays the Power Flow
Vector as explained in Ramo & Whinnery. The arrow on the slug
indicates the direction of the Power Flow Vector. The reading
of the meter indicates the magnitude of the Power Flow Vector.
The Bird is indirectly measuring [(E^for) x (H^for)] as forward
power and [(E^ref) x (H^ref)] as reflected power.

> Well, it's true for me and probably for most other people who have a

But everyone except you and a handful of others recognize the
fact that RF joules/sec and RF joules are virtually interchangeable
since EM energy cannot be stored in any condition other than as
EM energy traveling at the speed of light and real time cannot be
stopped or slowed down or speeded up (under normal circumstances).
Your statement that "there is no before and after" is a clue
to your misconceptions. If there truly was no before and after,
the modulation of our RF signals would never make it to the antenna.

> It's like this. Let's say you're riding your Harley through town at 50
> MPH ...

"I couldn't possibly be going 50 MPH - I only left home ten
minutes ago." :-) Believe it or not, that's exactly your argument.

Are you going to deny that the cross product of E^ x H^ is a
vector? You will have 1000 buried mathematicians rolling their
eyes in their graves (according to Richard C).

I think I'll stick with just saying that power, as a scaler quantity
does not have direction and cannot be negative. I have no argument with
you about vector quantities - as much as you'd like folks to believe
that I do. Thanks but no thanks, bubba.

Now taking applications.

Hi Fred,

It takes a condition called irony-deficit disorder to wade into these
things and say that. ;-)

Let's just give an example of the straight-man's lead into the joke:

"I flipped the switch to a 100W light Bulb.
What direction vector is the optical power?"

The Scientist would ask for this in standard notation, but we all know
that he isn't going to get that - hence, the subject from the
beginning is a joke. Now, only to wait for the punchline:
(drumroll) Ta-ta-dum....

Do a search for Alpha Delta. They make a variety of antennas, included
those specialized for shortwave reception. Very rugged construction.
Reasonable prices. (Used to have one of their SW slopers -- good
antenna.)

I was hoping someone would assert such. E^for is proportional to
Vfor which is what the Bird samples. H^for is proportional to
Ifor which is what the Bird samples. Within a 50 ohm environment
that yields forward power. Same for reflected power.

Richard Clark jested:
"I flipped the switch to a light bulb. What direction is the optical power?"

Seriously, away from and toward are directions. We expect a light bulb to be an energy source. If it becomes a sink it has a negative effect.

From John E. (Here`s Johnny!) Cinningham`s "The Complete Broadcast Antenna Handbook", page 243:
"Again, if the base impedance is a negative number, this merely means that energy is flowing out of a tower (toward the transmitter) instead of into it (from the transmitter)."

Sign is certainly used to indicate the direction of energy movement or the same thing, power flow.

Hi Richard,

You may disagree with the contents from this tome, but the citation is accurate.

>P=EI cos theta, where theta is the angle between E & I. For 0-deg. coa
>theta=1.

The section preceding distribution is Section 10, Power Plants, which devotes Para. 722 Inherent regulation; Para. 724 The Load Factor; Para. 725 Load Fluctuation; Para. 726 The Power-Factor. Sections10-795 through 836 is given over to AC switching.

And of course casting back towards the beginning of the Handbook we find ourselves at Section 7, Alternating Current Generators which covers Power-Factor, Slip, Stalling torque.... The treatment later in the section covers representative efficiencies in Polyphase equipment up to 1000HP well into the 90's of percent. All may note that this is an accuracy that is still 10 times better than the "Can you solve this" math offered here.

Returning to Section 11, Power Transmission; coverage there includes Power-Factor Correction. Para. 95, in part:
The per cent, quadrature current required for unity power-factor [which renders the formula responded to as accurate] at the receiver may be determined from Fig. 14, or may be calculated for a three-phase system as follows.... [which I won't go into but covers power-factors from 60% to 95%].

There is still no requirement to fill the need for a vector of direction.

This relates, in part, to my service in the Power Industry designing power grid control systems and testers (SCADA).

Hi Richard,

Where does he equate phase with direction? If I observe a negative phase shift in an otherwise pure cycle on wire-pair, does Terman teach that Power is flowing backwards?

Having used Terman's work as the basis for the course of instruction in the Navy, no such concept has ever been offered. 50 years after his last opus, and several years after his death is rather late to start claiming Terman missed the train - and should have said it.

I can appreciate that you have missed the disjoints of testimony that have lead from offering pi = 22/7 to the conclusion that the earth is flat, but don't get caught in responding to the flurry of uncorrelated statements offered to fill the void of accurate reporting.

We`ve been through detailled explanations of how a Bird works. Cecil did not need to do another. The wattmeter takes actual samples of the voltages and currents at any single point on the coax. These are representative of the powers which are moving toward the load and away from the load. Careful calibration allows indicarions in watts.

An electric current through a speedometer is calibrated to indicate miles per hour. It works. So does the Bird Wattmeter.

Hi Richard,

We are speaking of a load, often times an observer for optics, not a source.

Then there is a serious answer to the observer standing in the field of illumination and noting that there is power towards him, and power away from him. This is a very ordinary occurence with a light bulb that is within everyones common experience.

The light bulb in a room illuminates all the walls, the ceiling, and the floor. The observer occupies some portion of that 3-space and can confirm the "away from and toward directions." Still and all, the two powers do not vectorally add to zero. If this is confounded by stating that there are reflections, remove all such artifices and do this in the void of space. The net result is that there is still no vectoral addition that blacks out the light bulb simply because you can exhibit "away from and toward directions."

There is still the mathematical representation of the direction using standard notation if you want to take a swing at that. Again, what is the vector of direction for the light bulb? Absurdities abound in this discovery.

Hi Richard,

Certainly, but nowhere does Terman instruct us that this vector is a direction, it is a phasor. The coincidence of direction is imposed by the termination, not the math - hence the math is exclusive of such representations of direction.

However, let's discard that difference as a triviality to examine the original proposition thus:
To obtain a complete cancellation it requires identical powers with identical but opposing phases. You would agree that without this condition there is no complete cancellation?

Richard Clark wrote:
"Again, what is the vector of direction for the light bulb?"

Electromagnetic waves include light and heat whicjh have extremely short wavelengths. The light bulb may not be a perfect point source but the waves travel away from the source with the velocity of light and consist of electric and magnetic fields that are at right angles to each other and also at right angles to the direction of travel. Wave energy is divided 50-50 between the electric and magnetic fields.

Many frequencies (colors) make up the radiation from a light bulb. Much more heat is radiated than visible light.

In a radio wave the essential properties are frequency, intensity, direction of travel, and plane of polarization, For the constituents of light bulb radiation, it is the same.

300 million m/sec is the velocity and this equals the product of frequency X wavelength. Emissions of a light bulb are of extremely high frequency but of extremely short wavelenggth too.

All points on a wavefront are equidistant from the source and emerged simultaneouslly so they share the same phase.. From a point source light bulb we would be in the far field.

The field is transverse. The power flow (J.D. Kraus` words), or Poynting vector, is entirely radial.

The Bird does not generate a vector cross product. There is nothing
inside the instrument that's capable of doing such a thing.

The hardware displays readings of detected RF voltages - not power. The
forward/reflected power calibration on the meter scale is an external
calculation, based on transmission line theory.

You know exactly how instruments like the Bird work, because at various
times you have posted accurate descriptions here. Your enthusiasm for
your pet theory is making you distort the truth.

>Many frequencies (colors) make up the radiation from a light bulb. Much >more heat is radiated than visible light.

Hi Richard,

Actually that is quite wrong. IR is not heat, it is radiation. Heat, actually phonons, constitutes something less that 10% of the conversion of electrical power in a light bulb. Lest we take off on the tangent of IR bulbs being used for heating, it is the load of that IR radiation (directed upon a dissipative surface) that renders phonons, otherwise IR is radiated in exactly the same manner as any radiation. There are any number of simple, practical tests to confirm this. For one, IR passes through most glass without heating it. You have to go out of your way to obtain IR blocking glass (which doesn't even absorb that much either). There are some IR wavelengths that go right through water, and others that are entirely absorbed.

However, this is not about heat, nor IR, nor even the loss of a principle vector property, its angle notation, or even the whole absence of the vector property from the solution to wave interference powers. Rather, it is about the facade of complete cancellation

Entirely ignoring all these other trivial details, that cancellation is incomplete in and of necessity for real or imagined initial conditions. This is revealed in any mathematical solution, and certainly by examination.

The difference is that nobody is trying to create a complete distortion
of the way a speedometer works.

I am not criticizing the Bird 43 at all. I own one, and use it
regularly. It is a clever concept, well executed and with lots of good
features.

My objection is against the "other Bird 43" - not the real hardware, but
a piece of vaporware that is called a "Bird" but only exists in
someone's imagination. Somehow, this imagined instrument can truly
measure how much power is flowing in the forward and reverse
directions, and those measurements can be used to "prove" some point
about transmission line theory.

The real-life Bird 43 cannot do that. Its indications of "forward and
reflected watts" are only printing on the meter scale. They come from
calculations that are totally dependent on transmission line theory, so
they cannot be used to prove anything *about* that subject.

You cannot prove a theory by using evidence that depends on the theory
you're trying to prove. That is just simple logic.

The real Bird 43 is a good and useful piece of test equipment... but
nobody should buy that "other" one.

A light bulb does not emit coherent light so your
statement is 100% irrelevant to coherent RF sources
and/or coherent laser sources.

All part of the reflection model. Ramo & Whinnery go so far
as to present separate Poynting vectors for forward and
reflected powers where Pz-/Pz+ is the power reflection
coefficient.

The big difference is that a light bulb doesn't emit
coherent light. Coherence is a requirement for
superposition and wave cancellation. The light bulb
example is simply irrelevant to what happens with
a single frequency coherent RF transmitter or a
single frequency coherent laser.

Didn't say it did, Ian. Using valid assumptions like E/H=Z0
and E-field forward + E-field reflected = E-field total,
the multiplication is performed by a combination of phasor
addition, linear addition, and non-linear scaling. It is
an analog calculator.

> The hardware displays readings of detected RF voltages - not power. The
> forward/reflected power calibration on the meter scale is an external
> calculation, based on transmission line theory.

Yes, based on samples of a voltage proportional to the E-field
and samples of a current proportional to the H-field. Given the
basic assumptions of the Bird, it can be proven mathematically
that the Bird is displaying E-field x H-field for forward power
if the slug arrow is pointed in the forward direction and
displaying E-field x H-field for reflected power if the slug
arrow is pointed in the reflected direction.

> You know exactly how instruments like the Bird work, because at various
> times you have posted accurate descriptions here. Your enthusiasm for

The Poynting Vector is ***NOT*** my pet theory, Ian, it is
mainstream RF engineering.

All I am saying is that the Bird samples a voltage proportional
to the E-field and samples a current proportional to the H-field.
It then performs analog calculations on those parameters.
If you think you can disprove that statement, be my guest.

That's not true, Richard. If zero reflected energy reaches the
source in a system with reflections, a Z0-match has been
achieved. For a Z0-match to be achieved, 100% wave cancellation
is necessary. For all the nearly perfectly Z0-matched systems
out there, near perfect wave cancellation of reflected waves
has been achieved.

As you begin to admit when challenged, the instrument itself does nothing but add or subtract RF voltages derived by sampling the line voltage and current. No multiplication is involved.

The calibration to indicate power is performed ENTIRELY on the meter scale. But the instrument didn't do the multiplication or the I^2R calculation, so it didn't actually measure power.

>It is
>an analog calculator.
>
No, it isn't. The guy who drew the meter scale did the power calculation. The instrument itself is incapable of multiplying anything.

Ah, the old bait and switch trick.

In your earlier statement you said it "performs multiplication", which is totally false. But for your final paragraph you've switched it to "analog calculations", which is more general and thus partly true; and then you invite me to disprove that.

Cecil, I don't think you even realise you're pulling these dishonest debating tricks... but after too many years to count, I just don't have any more time for them.

Ian White, G3SEK wrote:
"In your previous statement you said it "performs multiplication" which is totally false."

It gives the right answers so it is not false.

Multiplication is the process of finding the product resulting from the addition of a given number by a certain number of times as there are units in another number.

It`s the product that counts, not the way you get there. An amplifier with a certain gain is fine. A lever that trades force for distance is fine. A digital machine, having no hardwired multiply and divide circuit and only works with ones and zeros is fine.

The only important thing is you supply representative inputs to a device and it gives you the correct product of the numbers as its outpot.

Best regards, Richard Harrison, KB5WZI

Hi Richard,

Well, your ability to research the topic continues well in advance of other's effort. Some may note the congruence of the specified emission peak and my statements earlier choosing exactly this same wavelength. This is called the eye's photopic response, but at night it shifts slightly to become more sensitive in its scotopic response. This is rod vision and occurs around the 510nM (5100ï¿½) wavelength or a pale blue.

The unintended consequence of this is that it suppress the eye's ability to perceive red light at night (why you see them used in dark rooms and WWII movies) which is something of a bummer for traffic lights and taillights (they have to be brighter than they would be normally).

Also, this discussion bears upon the answer to
"What is the wavelength of Glare?"
that has remained undiscovered by binary engineers. I bet our Readers can catch this clue. :-)

3115. Quagi for 446 ?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-21 20:20:04 UTC
From: rmccomb <rmccomb@adelphia.net>
Message-ID: <suidnTeiNNbknn3fRVn-iQ@adelphia.com>
Source record: 72981

I have recently built the identical twin to this quagi for 446 pictured here
http://users.adelphia.net/~rmccomb/images/100_0532.jpg
from the plans here:
http://commfaculty.fullerton.edu/woverbeck/quagi.htm
I understand the spacing and am curious how to wire the two together???
You may have read my old post. I am using 75 ohm line as it is all I
have available currently.
Any ideas will be greatly appreciated.

Soon to be liscensed

Richard Clark wrote:
"The unintended consequence of this (exposure to white light) is that it suppresses the eye`s ability to perceive red light at night (why you see them (red lights) used in dark rooms and WWII movies--..)"

I was in WW-2 and confirm that aboard my ship our chartroom (the compartment with an opening tp tje outside) indeed was illuminated with red lamps so that we would not be blind when we stepped outside. We were told that we used our cones in the daytime and our rods at night. How could I ever have remembered that?

From Lincoln`s Reference: Glare is said to reduce the ability to see, and hastens fatigue. Glare is wasted since it lowers the effectiveness of useful light. Glare is high light energy over a measurable period of time from above normal angles of vision (30 to 90-degrees above the vertical). I think this means you don`t want a bright light shining in your eyes. It`s glaring and impairs vision for awhile.

I wasn`t a signalman but I noticed our signaling light was fitted at night with a red filter called the "Nan-gear". Our phonetic alphabet in those days went: able, baker, charlie, dog---nancy. I suppose Nan was short for nighttime gear. I speculate it was hoped that the enemy would step out of white lighted quarters and not notice our red signal beams. So much for red lights and glare.

It probably wouldn`t work, but you might say to the policeman: I didn`t see the red light. The white glare desensitized my eyes!

Best regards, Richard Harrison, KB5WZI

Ryan- one thing to keep in mind about this Quagi antenna is that, Wayne designed it for weak signal work (read SSB/CW, at 432-435 (oscar) frequency range . Yagis, and presumably yagi- quads are not noted for great bandwidth . The elements for this will be SHORTER than the ones for 432! Also, that you want it for 446 MHz, tells me that you want to operate on FM, which is Vertically polarized (yagi elements in a up-down direction) the Original quagi was designed tor Horizontal polarization (elements left-right!) , meaning that the antenna needs to be flipped 90 degrees! You might have to find a webpage, or a design article for the quagi , as it is used with an FM rig. To NOT turn this 90 degrees, would actually caus a loss of 20 dB (1/100th the power), not gain! They will work on fm, but need to take this into consideration. Hope this helps, and BTW, the reasons that fm uses Vertical Polarization has to do with the ease of omni directional antennas, while, horizontal , for weak signal work has to do with lower noise levels on recieved signals, and the need for mazimizing the signal strength of weak signals Hope this helps, Jim NN7K

Hi Richard,

Your continued research into the topic that the originator could not identify reveals the problems of Glare being a subjective response and not a technical specification.

However, I have already provided technical clues to answer:
"What is the wavelength of Glare?"
that has so far evaded absolutely any response from our binary engineer.

So far the suggestions have been that it matters to a WHO, and there is a practical WHY to reveal the WHEREFORE. The differences in Photopic and Scotopic vision narrow down the wavelength, but there is a vast gulf between them. Even being a binary choice, there is still the chance of being wrong that puts the gag on his stepping forward with an answer. In the end I will be alone in completing this I suppose. It will cap off my full mathematical treatment and the exposure of this full cancellation that is TEN TIMES BRIGHTER THAN THE SUN ;-)

This topic of Glare, being his alone, has subsequently been identified by him as being inconsequential detail, or better yet, wholly from my distorted imagination (but only when I examine this point).

There is still much to mine here. With errors so abundant, it is difficult to choose any one aspect and not have to correct three aspects of its distortions.

OK. For a police state to exist, the second step is saturation
video surveillance of the downtown area of your capital.

The third step is to destroy the public library system through
non-judicially-supervised, on-demand, secret surveillance.

A lot of the "security contractor" thing is a charade anyway.
Before the stop-loss insanity, many of the qualified smart grunts and
their officers bailed out of the military and formed, or went to work
for, the "contractors" for the larger salaries. Then we have the gall
to express horror when these "civilians" are targeted. They've only
changed uniforms.

Hal:

Actually, I have used the coherer on receiving antennas, in a couple of lightning storms it has indeed shorted to ground and needed to be shaken to restore the signals from the antenna (NOTHING near a direct hit and this is central cal, not much lightning and of little significance.)

Presently, I use MOV's... at best, -=maybe=-, better than nothing...

<invalid@invalid.invalid> wrote:

>Go and take a look.

That could be a dangerous suggestion, as seen at
<http://www.lhup.edu/~dsimanek/horse.htm> which contains a few
additional comments as to the source.

In part, it reads:

In the year of our Lord 1432, there arose a grievous quarrel among the
brethren over the number of teeth in the mouth of a horse. For
thirteen days the disputation raged without ceasing. All the ancient
books and chronicles were fetched out, and wonderful and ponderous
erudition such as was never before heard of in this region was made
manifest. At the beginning of the fourteenth day, a youthful friar of
goodly bearing asked his learned superiors for permission to add a
word, and straightway, to the wonderment of the disputants, whose deep
wisdom he sore vexed, he beseeched them to unbend in a manner coarse
and unheard-of and to look in the open mouth of a horse and find
answer to their questionings. At this, their dignity being grievously
hurt, they waxed exceeding wroth; and, joining in a mighty uproar,
they flew upon him and smote him, hip and thigh, and cast him out
forthwith. For, said they, surely Satan hath tempted this bold
neophyte to declare unholy and unheard-of ways of finding truth,
contrary to all the teachings of the fathers. After many days more of
grievous strife, the dove of peace sat on the assembly, and they as
one man declaring the problem to be an everlasting mystery because of
a grievous dearth of historical and theological evidence thereof, so
ordered the same writ down.

Francis Bacon, 1592.

Ian White G/GM3SEK wrote:
> As you begin to admit when challenged, the instrument itself does
> nothing but add or subtract RF voltages derived by sampling the line
> voltage and current.

You missed the point, Ian. THE VOLTAGE SAMPLE IS DIRECTLY
PROPORTIONAL TO THE E-FIELD AND THE CURRENT SAMPLE IS DIRECTLY
PROPORTIONAL TO THE H-FIELD. Given the assumptions about the
boundary conditions in which the Bird is placed, the Bird is
INDEED indicating the value of the Poynting Vector no matter
how indirectly. IF IT WASN'T, BIRD COULD NOT REMAIN IN BUSINESS.
That's what Bird Wattmeters do - indicate the magnitude and
direction of the Poynting Vector - assuming the instrument is
properly used.

Pz+ = E^for x H^for = Bird wattmeter reading for slug ==>

Pz- = E^ref x H^ref = Bird wattmeter reading for slug <==

This is all covered in "Fields and Waves ..." by Ramo and
Whinnery. I have NOT introduced anything new. I have simply
tied together some loose ends from all the references available.
Anyone with an open and logical mind could have done exactly
the same thing.

> No multiplication is involved.

On the contrary, non-linear calibration of linear meters is an
old technique for analog multiplication. I assumed you knew that
already, but maybe you are not that old. When I was in college,
we put a '1' mark at one milliamp. We put a '4' mark at 2 milliamps.
We put a '16' mark at 4 milliamps. It's a very, very, very old
technique for analog multiplication.

> The calibration to indicate power is performed ENTIRELY on the meter
> scale.

EXACTLY!!! YOU GOT IT!!! THAT'S ANALOG MULTIPLICATION!!! I did the
exact same thing for analog multiplication when I was in college.
Non-linear calibration of linear meters is a very, very, very old
analog computing technique. Do you even remember analog computers?
If not, I can loan you my analog computing college textbook.

>> It is an analog calculator.
>>
> No, it isn't.

Yes, it is. I learned all those analog techniques while in
college at Texas A&M in the 50's. Maybe you should review
a very old reference on the subject. When I was in college,
analog computers were more popular than digital computers.
Op-amps using tubes were more numerous than anything digital
(and the Texas A&M mascot was a T-Rex). You young sprouts are
just digitally-spoiled brats. :-)

> In your earlier statement you said it "performs multiplication", which
> is totally false. But for your final paragraph you've switched it to
> "analog calculations", which is more general and thus partly true; and
> then you invite me to disprove that.

It INDEED does perform analog multiplication, Ian, through the non-
linear calibration of the linear meter. I'm not trying to confuse
anyone. I just assumed you knew that already. Some of the OF's on
this newsgroup can verify what I am saying.

> Cecil, I don't think you even realise you're pulling these dishonest
> debating tricks... but after too many years to count, I just don't have
> any more time for them.

Your ignorance does NOT equate to dishonesty on my part, Ian.
Is admitting ignorance ever worth sacrificing integrity?

> <plonk>

Ian, instead of plonking me, as Roy did, why don't you just prove
me wrong? Wouldn't that be extremely easy given how wrong you assert
that I am?

Apparently, Ian is too young to remember analog multiplication
by non-linearly calibrating the face of linear meters which is
exactly what Bird does.

If that source were entirely coherent, superposition
between the forward waves and reflected waves would
result, obeying the laws of physics. Some areas could
be very bright obeying the total constructive interference
equation. Some areas could be totally black obeying the
total destructive interference equation. You really
should read _Optics_, by Hecht and get back to us.

The above is EXACTLY how antenna radiation patterns
are achieved.

Actually, the Poynting Vector is extremely well defined *AND* well
accepted in the RF engineering community. Do you really reject the
Poynting Vector concept? If so, that explains everything.

You're still presenting that straw man riding that dead horse.
Please read my lips, Jim. *ENERGY CANNOT BE CANCELED*!!! Waves
can be canceled but the energy in the canceled waves must
change direction in a transmission line because there are
only two directions available. When fields cancel in one
direction, the energy in the fields must be re-distributed
in another direction. Given two, and only two, directions for
that re-distribution in a transmission line, what is it about
the following that you refuse to understand?

"... when two waves of equal amplitude and wavelength that are
180-degrees ... out of phase with each other meet, they are not
actually annihilated. All of the photon energy present in these
waves must somehow be recovered or redistributed in a new direction,
according to the law of energy conservation ... Instead, upon meeting,
the photons are redistributed to regions that permit constructive
interference, so the effect should be considered as a redistribution
of light waves and photon energy rather than the spontaneous
construction or destruction of light."

Source record: 73001

http://www.tfn.net/~gfloyd7/antenna

I'm interested in a wire gain antenna for 6m SSB, and the design above looks like a pretty quick project. Is it possible to use a j-pole like this above efficiently as a horizontal antenna? Couldn't it be center-fed with, say, 2 collinear half-wave sections seperated by 1/4 phasing stubs? In doing so, I was thinking of feeding the center with 300 ohm balanced line.

Thanks for any thoughts.

Richard, you apparently are not reading my postings. The
wavelength of glare is exactly the same as the wavelength
of the single-frequency coherent laser forward wave
emissions. Do you want me to re-post the equation for
wavelength Vs frequency?

Cross-posted to: alt.cellular.tech,rec.radio.amateur.antenna

Hi folks
I'd like to know more about the antennas that are in many of the
multiband cellphones today.
A lot of the phones are multiband,(some are multimode), yet they have
only one antenna.
Would i be correct in assuming that most such phones have an
omnidirectional antenna which is tuned for centerfreq(computed by
considering all the bands for the phone)
If so did the RF frontend designers had to compensate for the fact that
the antenna may have a different vswr at different frequencies...
Or there are dual/tri/quadband antennas in such phones.

Also if you can reccomend some good books/website on this topic that
will be great.
Thanks In Advace
-EOS

If I ever said, "Power cancels at a Z0-match", I made a mistake.
I don't think I ever said that and I believe that to be only one
of your numerous straw men, but if you will provide a valid reference,
I will take it back and appologize for my mental mistake. I am not
perfect, BUT the onus of proof is upon you. You can provide a reference
for your assertions, can't you, Jim? :-) (In case you missed it, this
is a challenge to your integrity.)

3150. Re: Horizontal J-pole?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-22 02:08:30 UTC
From: Hal Rosser <hmrosser@bellsouth.net>
Message-ID: <lxYDe.13020$do5.11738@bignews5.bellsouth.net>
Source record: 73016

A jpole is a end-fed halfwave - and because of that, lends itself well to
vertical applications.
It could just as well be oriented horizontally,
but
for a half-wave horizontal antenna,
a run-of-the-mill center fed dipole may be in order.
feed it directly with coax from the transmitter.
or not
(long runs may deserve twin lead or ladder line)

Won't the vertical collinear still win over the dipole because of gain,
on the order of 3-6 dbd?

Now somewhere I've seen a center-fed horizontal antenna. something like
a double Zepp, but in addition to feeding the two halfwaves on each
side, there is additional halfwave sections added to each end via 1/4
wave phasing harnesses, or maybe I'm just imagining something from an
old antenna handbook.

You have described a horizontal colinear antenna. It has gain broadside
to the wire but don't expect good results off of the main lobes.
Of course if you have a preferred direction, or work two locations 180
degrees apart it works nicely.

Just picked up a High Sierra 1500 at a hamfest this last weekend. Great shape but no manual. Sent an email to High Sierra but was told that they only have the manual for the 1800 and 1800/Pro now. They had a hard drive crash and it was the only place they had the manual, so, now there are none available.

Anyone have a manual they would like to sell? How about making a copy for which I would gladly pay along with the cost to get it here.

If anyone can help let me know, please.

Thanks in advance.

Since, in my example, glare has been completely
eliminated, you are asking: "What is the wavelength
of nothing?" My guess is that it would be the same
as the wavelength of the sound of one hand clapping.

In my example, if we increase the thickness of the thin
film to 1/2WL, it will maximize the glare to 2% of the
incident laser power. In that case, the glare would be
the same wavelength as the single-frequency coherent
laser. In the mental example, the wavelength doesn't
matter so 632.8 nm might be a logical popular choice.
I have a collimated laser of that wavelength.

Hi All,

At 433 MHz UHF, I need to reduce the lenght of the dipole using loading coils or a better method.

I need to know if there is a antenna program or a method to determine values and location.

tnx de KJ4UO.

I would like to make it half-size.

Can I just take the full-size dipole and roll the extra copper into a coil in the center?

If you wind the helical coils with large spacing between turns--pretty close...

The capacitance across the windings of the coils will be the most notable effect, and will induce a need to shorten the electrical length of the element conductors, keeping that capacitance to a minimum may allow this need to be insignificant. If not, just trim wire length a bit.

Best might be to set up with a "wand" which can be lengthened or shortened a bit on each element which is so shortened by a coil.

Loading coils do NOT shorten an antenna! They electrically lengthen an antenna that is already physically too short.

What do you really want to accomplish?

WRONG

This isn't even within the range of the two wavelength clues offered.

Dear Readers,

Let's examine why this answer is so wholly lacking:

1. The wavelength described, as already noted, is a wild foul out of
the ballpark;

2. a popular choice? This conjecture is broadly announced with the
characteristic couching of terms "might be" to hedge the answer. My
later discussion will reveal why no one would choose this at all;

3. logical choice? Absolutely no logic is offered - hence it is
exactly what it appears to be - a wild guess, My later discussion
will point out why this has no basis in logic whatever;

4. the wavelength doesn't matter? Given this is application driven,
the topic of Glare being just that, Glare is highly specific to
wavelength and is very intimately associated with perception. These
are two areas of discussion that exhibit considerable errors.

Naturally I will tie this all together in later discussion in a new
thread. And I will show:
"What is the wavelength of Glare?"
the answer of which has already been posted by me (see above) ;-)

No you can't.

Program ADDALOAD calculates the value of a loading coil to resonate an
antenna wire of given length at any frequency. The location of the
coil as a fraction of length along the antenna wire can be chosen in
advance.

That's if it's possible of course. In some cases a loading capacitor
is needed.

You will need a coil in each half of the dipole.

Download in a few seconds program ADDALOAD from website below and run
immediately.

But in order to conserve energy, wouldn't the glare have to re-reflect off of an interference pattern and continue - I mean - start moving in the forward direction? ;-)

Glare occurs entirely internally to the eye, and there are two main types of glare effects. The first is the corona, which forms the fuzzy glow you see around a light at night, or the rays which seem to shoot out from the light of the sun. The second is the lenticular halo, which is only seen when the pupils are dilated enough and is a color banded halo which is usually visible surrounding the corona.

There are times when Google search is great, and others where it fails me. This is one of those situations.

I'm trying to find out what people recommend for handling both APRS and voice radios in the same vehicle. I want to have two separate rigs, one dedicated to APRS, the other for normal voice comms. I'm concerned about receiver overload and frying one of the rigs when the other is transmitting at high power.

The rigs are modern (Yeasu FT-2800 for APRS and Yeasu FT-8900 for voice). Would the intermod rejection of these two rigs protect them? I'd rather not set up a cavity or other expensive filters.

How do others have this setup in place?

Hi Fred,

Yes, this is another reason why using physiological characteristics to
explain otherwise dry, technical issues is so fraught with error.
That error is because not everyone perceives the "problem" (being
"Glare" here) in the same way. Further, within the population of
readers here, cataracts and "Glare" are a very common issue that is
wholly unrelated to the treatment of thin film interference and
"Glare."

I have spent a number of years in designing optical system to reduce
what is called "Glare" in this technical sense. In other words, the
suffering component was an artificial eye, so to speak, a
Photomultiplier Tube (PMT) within a fluorescence detection system that
achieved accuracies in the hundredths of percent. The abysmal math
performed in relation to this topic is amateurish in the extreme,
especially considering that so little more work was needed to offer
vastly better results.

It has been quite obvious that this poor math was necessary to support
a faulty premise: complete cancellation. There is no such thing,
especially within the context of "Glare."

Actually, I got that wavelength from _Optics_, by Hecht.
Hecht says: "The He-Ne laser is still among the most popular
devices of it kind, ... (632.8 nm)." So your argument is with
Hecht, not with me. Good luck on that one.

> off of an interference pattern and continue - I mean - start moving in
> the forward direction? ;-)

Wave cancellation causes the re-reflection but you are essentially
correct as described perfectly on the following web page. Note that
there are only two directions in an RF transmission line. If the energy
stops moving rearward, as it does at a Z0-match, then it must start
moving forward. Walter Maxwell explained all of this decades ago.

http://micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index
.html

"... when two waves of equal amplitude and wavelength that are 180-
degrees out of phase with each other meet, they are not actually
annihilated. All of the photon energy present in these waves must
somehow be recovered or redistributed in a new direction, according to
the law of energy conservation ... Instead, upon meeting, the photons
are redistributed to regions that permit constructive interference, so
the effect should be considered as a redistribution of light waves and
photon energy rather than the spontaneous construction or destruction
of light."

This applies to single frequency coherent glare (reflections). You see,
Jim, the field of optics has no virtual reflection coefficients for
you to hide behind. A change in the index of refraction *always* causes
a reflection in optics. The only possibility of eliminating that reflection
is through wave cancellation. A change in Z0 also always causes a reflection
in RF transmission lines. An S-parameter analysis acknowledges that
fact of physics. Too bad so many RF engineers rely on a virtual
reflection coefficient as a cause when it is merely an end effect.

Of course, in reality there's no such thing as complete
cancellation. But we can get the cancellation so good
as to be virtually perfect.

There's no such thing as a lossless transmission line,
yet you seem to have no problem with that concept. I
would venture that an SWR of 1.01:1 is close enough to
complete cancellation to be declared as close as humans
need to come to perfection which means that you are
just blowing smoke.

I'm sure you are a glare expert and I'm just as sure that your
postings on glare are completely irrelevant, an obvious diversion
in your feeble attempt to change the subject away from what is
important. Why are you so afraid to deal with my example including
the boundary conditions? Why are you so accepting of an ideal
transmission line yet so unaccepting of an ideal thin-film?

There's no such thing even in a perfect world. Adding qualifications
like "in reality" changes nothing. The poor math treatment you
offered is not justified by appeals to conceptual arguments. Being
conceptual still allows (as I have demonstrated in the actual math)
them to be far from immaculate conception. We've seen you assume the
name of Occam, Galileo, Newton, but not Madonna. ;-)

Chuck, Flame disclaimer - This is not a comprehensive tutorial on all types of antennas or matching or all causes of loss and gain. I have simplified things for the purpose of providing a simple to understand explanation of this antenna which can also be used as a basis for further knowledge. Adding all possible theoretical and practical consideration up front only serves to confuse. With this knowledge (model in your brain) you should be able to understand things well enough to understand this antenna and other, related types (of which, almost all are).

To the point
Short answer:
Yes, you can feed it at the end, or for that matter, in the center of a 1/2 wave section with balanced line and a tuner/matching device.

...or at the center stub...or, wherever, with suitable matching...

(and long answer):
The "J-Pole" as most now call it, or as I prefer to call it, simply the "J-Antenna", is been around for along time and nothing more than an end fed half wave. I have instruction for a 20M J in my 1945 handbook. It is the same antenna as the standard half wave "dipole", just fed on the end rather than the center. The end is a high impedance feed point and therefore requires something to get to/from the 50 ohm rig. The pseudo 1/4 wave "stub" where the feedline connects is that impedance matching device. I call it "pseudo" because I believe an exact analysis yields that it is not precisely 1/4 wave for a perfect match, but close also counts in antennas as well as horse shoes. End feeding probably skews the pattern a little, but a half wave is pretty much a half wave regardless of how you feed it. You can run it horizontally of vertically. The pattern moves accordingly, taking the doughnut shape from the "wheel" orientation to the "inner-tube-floating-down-the-river" orientation, respectively.
The link you give shows "two half waves in phase" also end fed. This is called "collinear" since they share ("co") the same line ("linear"). Like the name "coax" meaning the two conductors share ("co") the same axis ("axial").
The "...in phase" part of this is because of that 1/4 wave stub in the center of the two 1/2 wave sections. It gets the two 1/2 wave sections in phase by providing 180 degrees of phase shift at the ends where it connects to the 1/2 wave sections and the stub is not supposed to be part of the radiating system. This makes the "left" ends of each 1/2 wave the same polarity (same story with the right ends). You can keep stacking these up just by adding the stub and 1/2 wave section. By the way, this is a common antenna configuration (half waves in phase) that you see mounted vertically on the three sides of all the triangular cell towers.
Adding half waves, most certainly lowers the feed impedance, so

adjustments in the matching device/method are needed as you add them.
If you choose to feed the first one in the center, it starts as the
standard 1/2 wave dipole". If you choose the "J" matching method, it
becomes the "J-whateverYouLike" antenna. As you add 1/2 wave sections, the
pattern will become narrower along the broadside. Starting from the
"dipole" you can add them to both ends, preferably symmetrically. As the
radiation from each of these 1/2 wave sections gets out into space, they add
up in the broadside direction and cancel in others. This squirts more of
your power there and less in other directions, giving gain in that direction
(and loss in the others) -- You squish the inner tube flatter. Each time
you double the length of the whole thing (the physical length of the 1/2
wave radiating sections), you realize approximately 3 dB gain in the
broadside direction. This 3dB diminishes for each subsequent doubling, but
is an ok approximation.
Feeding antennas with open wire, or balanced line is preferred when using
an antenna on several bands, or (which is the same basic reason) where the
feed impedance is far from 50 ohms, or expected to be. This is to keep
losses low since it is expected that there will be a high VSWR on the feed
line and the matching will be done away from the antenna, most commonly, at
the transmitter.

The British have always been under the impression that
we Americans saved our pennies for the sole purpose of
sending them to the IRA to finance the IRA's terrorist practices.
This is news to those of us who lived through the whole
era without giving anyone anything, or even taking sides
on the issue. There may have been a few Irish expatriots on
the East Coast who contributed to the IRA during that time,

but, for most Americans, it was a struggle that just didn't
register.

I have always used the CFA as a mobile antenna!

Get with the program people, you will be hard pressed to find a better antenna for this purpose!

As a shack antenna, it sucks!

However, what other antenna can you chuck a motor into, slap a steering wheel and horn on and drive?

You guys are all wet, as usual... <satisfied-smirk>

Sorry, that doesn't work. A length of stretched out wire doesn't behave the same when it's wound into a coil. The reason is that the field from one turn of the coil couples strongly to the other turns, while the field from a straight wire couples only weakly to the adjacent regions of straight wire. That's why a coil has more inductance than a straight wire of the same wire length.

The problem with using a simple program to answer your question is that at that frequency any coil is likely to be a sizeable fraction of a wavelength long, and perhaps in diameter and therefore will radiate substantially. So a lumped inductance won't be a good representation of the coil. EZNEC's helix creation feature would let you realistically model any proposed inductor and get an accurate answer. Unfortunately, the free demo version won't have enough segments to do this. You can get more information about it at http://eznec.com. You could model some very simple helical inductors of a turn or two with the demo program to get an idea of how the program works.

3192. The Failure of Poor Concepts in Discussing Glare Reduction

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-22 21:22:32 UTC
From: Richard Clark <kb7qhc@comcast.net>
Message-ID: <rlm2e19c6e0irqmj20bj10lfgtpbs2leuu@4ax.com>
Source record: 72956

Glare (1):

In the context of matching for both Optical and ordinary RF applications encountered in the Ham Shack; it is meant to be described as the unwanted reflection of energy (or power, or what-have-you).

Glare (2):

In the context of the physiological response to observing unwanted reflections; it is meant to be described by applications that give rise to this annoyance. This can sometimes be confused with the first meaning of Glare that is suitable close, but can come into conflict with that meaning.

Glare, and Glare reduction:

When the topic of Glare is expressed in regard to the second usage, it is always wavelength specific, and application specific. In fact this is true of both meanings, but the commercial marketplace overwhelms by example in the second. With that in mind, we have to consider WHO is being served by Glare reduction. This is often the naive public who would otherwise be encumbered by Glare where their attention is drawn to it as it masks what is trying to be presented to them.

So, Glare masks the perception by reflections of light from, most usually, a pane of glass, plexiglass, or acrylic (and so on down the line) that covers or windows an exhibit. Usually we are speaking of covered art work, or display cases exhibiting samples or products (this being the most common form of Glare reduction application).

The quickest and most absolute method of Glare reduction in a showcase window on the street looking into a storefront is to simply tilt the window at the top, toward the viewer. This renders all light source reflections (typically higher than the head of the viewer) down. Ten or twenty degrees of tilt is often enough to give the illusion of there being no glass at all. Note my usage of "illusion" as Glare is all about perception in this second usage. This form of Glare reduction is wide-band and exhibits very little sensitivity to wavelength. The same Glare reduction of tilting glass covered artwork is also suitable for the same reason. However, I would point out that in such cases, the display staff make every effort that the lights be spotted on the artwork, otherwise if your face is illuminated, the artwork suddenly becomes a mirror.

Where both meanings of Glare converge for the same purposes, we find a more specific remedy. Specific because it employs tuned interfaces to reduce (not eliminate) reflections.

Here is where the convergence demands two different wavelength specifications, and importantly WHY. As I have offered elsewhere, there are two types of vision, Photopic and Scotopic (with a third, Mesopic, between the two which is the process of accommodation of migrating from one to the other - "acquiring" night vision is a commonplace description).

Anti-Glare materials that employ thin-film technologies seek to accommodate the major sources of Glare that fall into these two wide band regions of 550nM and 510nM. They are also application specific in that there are two forms of common illumination involved that compounds this to a four way solution. Those sources of illumination are Metal Halide and High Pressure Sodium lamps. There are others, certainly, but these specie exhibit characteristics that are extrapolated to similar sources.

Metal Halide lamps exhibit a comb of resonances, as does the High Pressure Sodium, that makes Glare elimination impossible. However, it does not make it impractical as among those major lines of emission, the optical engineer can select the biggest contributor such as 510nM for the night vision component of the eye's response. However, this doesn't make much sense because it also reduces the eye's ability to perceive what is being illuminated by that wavelength too. Not much night vision advantage in that, is there? However, when considering this is placed over artwork commonly, artwork exhibits a Lambertian distribution of reflected light, not a specular form of reflection. Hence the specular form exhibited by a pane of glass is reduced and the Lambertian reflection emerges with a greater contrast (another benefit of choosing anti-Glare products).

High Pressure Sodium, on the other hand, has a very strong line at the 610nM wavelength. This, too, would be a natural thin-film wavelength selection. In regards to night vision, such a reflection (that is, without Glare reduction) would be nearly invisible anyway. As such, its use would be oriented towards those WHO have a light adapted eye, that are in a darkened viewing situation.

However, as described, these are very poor solutions to the problem they attempt to answer. This is because these sources exhibit a comb of such wavelengths in their emissions. It follows that one interference layer may impact one line, but certainly not all (there being easily a dozen lines of emission for either source in either light adapted vision). Hence we have the multi-layer methods that my quote offered from the marketplace.

It should come as no surprise that anti-Glare products are wholly useless under common tungsten lighting whose bandwidth is broad and continuous. There is one exception, and it is commonly found for computer screen reflection reduction. I must note that such reduction has absolutely nothing in common with wavelength interference.

This class of reflection reduction employs a wide band light reduction. Principally it seeks to reduce all ambient light from

striking the display's surface and then reducing the reflections even further. This is a double whammy, where the display suffers it only once. However, you can control the brightness of the display to replace that loss, and in this sense you have increased your signal+noise/noise ratio.

Finally there is one source of reflection elimination that is common to both the optical engineer and the rf engineer (and apparently wholly unknown by binary engineers). I offered above one display window trick of tilting the top of the window towards the viewer. When this is done at a particular angle (and the ground below is not illuminated by the reflection - another feature of display window design), then there will be no perception of the window at all. Many people have knocked there heads against such windows trying to get a closer look at what was being displayed. Lawyers trumped designers by begging this was a possible source of litigation for those so injured. Some of these windows may yet survive in the older parts of your town where they cater to high-end shoppers. You may note that there are rails placed in the way to keep the curious from getting to close and bruising their noggins.

Now, I offered that there is a particular angle. For both the optical engineer and the rf engineer, it is called the "Brewster Angle." This is also known as the angle of maximum absorption and minimum reflection. When light or RF (it doesn't matter which) of vertical polarization strikes an interface at this angle, all of that energy passes through the interface with minimum reflection. When you perform a vertical antenna far field measurement, you may note that the lobe "sucks in" at the very low radiation angles. This angle that exhibits poor propagation results is a consequence of the air/earth boundary that is identical in all respects to an optical interface between two materials of differing indices. The optical engineer calls it the index of refraction/reflection (and can be examined through Snell's Laws); the rf engineer finds the same property in the ratio between the characteristic Z of air and the characteristic Z of the earth.

An instance to illustrate the rf scenario. With Air the Z is roughly 400 Ohms, for the Ocean it is roughly 10 Ohms. That ratio, in this case 40, results in a Brewster Angle of about 1ï¿½ï¿½. If we were to consider something more remote, and dryer like the ground in my neighborhood where the characteristic Z is closer to 100 Ohms (luckily I can see a vast body of seawater from my window); that ratio is 4 which results in a Brewster Angle of about 15ï¿½. Try as I might in directions other than towards Puget Sound, I will never launch any significant signals at angles lower than this 15ï¿½.

As a closing comment about the Brewster Angle, nearly every Laser uses this in their output window.

Richard:

Quite on topic, I commend you!

Yanno, back when I was a young feller, we lived in the sierra nevada foothills. I remember traveling to my favorite swimming hole on bicycle. It was over a five miles distant ride, but for the exuberance of youth, that was no distance what-so-ever.

And, gawd, how hot and ready for a swim we would be when we finally reached it on our bicycles.

Many times we would take fishing poles with us. Bluegill, trout and bass could all be caught in the creek there. I never cared for fish that much myself, but there was always a member of the family which was more than anxious to take the fish from our hands and make themselves a meal of it.

Other times we would take along 22 rim fire rifles and plunk around, shooting targets, bottles and cans. My favorite was a Remington rifle, single shot bolt action. I had a semi-auto but would go though ammunition faster than I could make money to replace it. Many of the other kids parents where not comfortable having their children around guns, so to their parents, we always kept such secret. Never an accident, and always behaved in a sane manner with weapons. I that my father to this day for the excellent instruction he imparted to me in handling weapons, and the great respect he inspired me to hold for them. When I was older, I purchased a 9mm german lugar, I still have it to this day, along with a 45 cal auto, both are favorite guns of mine. But, the stories of those guns are for another day...

Even did a little gold panning there. The area was a source of vast amounts of gold during the gold rush. To this day, gold can still be found in most any stream in that area. And, back then, there were still a few prospectors around which actually were able to eek out a living by sluicing the streams there and selling the gold to jewelers. Later in life I even bought a keen 8 inch dredge and went back. I ended up finding quite a bit of gold in those creeks and rivers with that dredge, a buddy and a couple of wet suits. Just loved to drink beer and float about dredging all day long. This is another fond memory of mine, but again, a story for another day...

Ahh, those days were some of the most favorite of my youth...

However, I digress here a bit.

So, this brings me to the important point of this post, and the point I had first set out to develop.

I once (well, maybe more than once) seen a glare on the water of that swimming hole...

Maybe you won't, but that doesn't mean it is impossible. A well-designed, well-implemented vertical can do that. If it couldn't, MW broadcast stations wouldn't have much of a groundwave.

Jerry - I'll second that idea. I use banana plugs on the balanced feedline from my inverted V wire antenna. If the weather looks like it might get bad, I just unplug it from my transmatch and throw it out the window (the feedline - not the transmatch!)

I'm sure Richard (Clark) is talking about sky wave. You're talking about surface wave. Indeed, a field is "launched" at all angles. But the portion at low angles (the surface wave) attenuates with distance, and the attenuation increases with frequency. At HF and above it's good for only a few miles, and all that's left beyond that is the sky wave, at higher angles. It is possible to get very low angle sky wave, but it requires vertically polarized waves and a very good conductor like salt water for several wavelengths from the antenna in the direction of propagation; favorably sloping terrain; or an extremely high horizontally polarized antenna.

As I'm sure you know, AM broadcast antennas intentionally radiate very little sky wave, and that's what amateurs need for communication beyond a few miles. Some care must be used in comparing MW broadcasting requirements and characteristics with amateur HF communications.

OOH!
If you want a 'gain' antenna - the easiest to do is a 5/8-wave for a
vertical, and you just add enough of a coil at the bottom to get your match
to 50 ohms. its hard to beat as far as verticals go..
and for a good gain horizontal antenna:
a double zepp - a dipole with both sides 5/8-wave - a total of 10/8 wave
(one and a quarter wave)
- but its fun to experiment with co-phased antennas -
I say - get a MFJ 259 and have fun playing.
I like quads and quagis.
but for vhf and uhf: the best improvement is height. - get that antenna up
high.

I always wondered why a simple Jeep wouldn't do. They are more maneuverable, cheaper to produce, and much more fuel efficient--not the the gov't cares. I can see where a heavier vehicle such as the Hummvee has a place, but then there's lots of jobs a smaller Jeep could do, too. (yeah, I am partial to the Jeep, but it is just MHO).

AM broadcast station verticals have very significant energy at elevation angles that can be propagated by skywaves. As I'm sure you know, Class A AM broadcast stations have an extended geographic service area served exclusively by their nighttime skywave--many times more area than is served by their surface wave, in fact.

Richard Clark's statement did not limit his conclusion to amateur HF communications.

I'm sorry, I stand corrected. Extended coverage AM stations do indeed produce significant sky wave as you've pointed out. I was thinking only of suppression of high angle sky wave radiation to avoid fading.

And you're also correct about Richard Clark's statement. Perhaps he is indeed attempting to do some MF broadcasting to his local area -- I just assumed he wasn't.

Since there's no such thing as a perfect world, that's a
moot point. But complete cancellation can certainly happen
in a human mind. All it takes is equal magnitudes and
opposite phases of conceptual EM waves. That's what makes
us different as a species.

You have taken a simple conceptual example to extremes.
Even more extreme is that there's no such thing as an
exact height, width, or depth, or an exact time, or a
point, line, or plane. There is no exact voltage, current,
or power except maybe at the quantum level. There is no exact
characteristic impedance. The list is endless. Why you choose
to engage in such silly diversions away from simple truths is
interesting. Taken to your extremes, nothing, including
communication among humans, is possible.

Indeed, "non-glare glass" was a misnomer and I appologize
for that mistake in word selection. Reflections, not
glare, was the actual topic of discussion. "Glare" or
"non-glare" does not even appear in the index of _Optics_,
by Hecht.

I should have called the thin-film function "non-reflective"
instead of "non-glare". Glare is actually totally irrelevant
to anything I have posted including the original example.

The IEEE Dictionary does not have that as a definition for "glare".
I made a mistake in calling my example a "non-glare glass" example
and I appologize for that poor choice of words. It was a semantic
mistake, not a conceptual mistake.

Richard Clark wrote:
"As a closing comment about the Brewster Angle, nearly every laser uses this in their output window."

A plane wave strikes the earth and its reflection leaves at an angle which equals the angle of incidence.

The strength of reflected wave to incident wave is a vector ratio called the reflection coefficient.

Strength of the fields just above the earth is the vector sum of the incident and reflected waves, taking into account both time phase and space orientation.

The reflection coefficient`s value depends on the characteristics of the reflecting surface. If the earth were a perfect reflector, the reflected wave would be as strong as the incident wave and the value of the reflectopn coefficient would be 1.

With a perfect reflector, the horizontal components of the electric incident and reflected fields exactly cancel (Terman`s words) at the reflecting surface. On the contrary, the vertical components of the electric fields of the incident and reflected waves do not cancel, but add together at small reflection angles.

For imperfect earth, magnitude of the reflection coefficient is less than 1, and the angle of the reflected wave will be slightly shifted.

The incidence angle has a complicated effect on vertically polarized waves. At grazing incidence, the reflection coefficient is 1 on an angle of 180-degrees. The reflected wave is as strong as the incident wave, but its phase is reversed by the reflection. However, with vertical incidence, the phase shift is very small and the reflection coefficient is less than 1 with real earth.

Between the extremes of grazing incidence and vertical incidence, magnitude of the reflection coefficient goes through a minimum at a small angle of incidence and reflection. It depends on the characteristics of the reflector (soil). This puts a small reduction of radiation at a low vertical angle called the Brewster angle.

At the Brewster angle, the magnitude of the reflection coefficient for vertically polarized waves will be much less than 1 and so tends to reduce radiation at some low vertical angle, but not at zero degrees..

My 19th edition of the ARRL Antenna Book calls this minimum in the vertical radiation pattern, the "Pseudo-Brewster Angle" (PBA) because

its effect was noticed in the reflection (glare) of sunlight from water surfaces when the sun was low. It was named for Sir David Brewster, a Scottish Physicist (1781-1868). PBA is described on page 3-6.

Best regards, Richard Harrison, KB5WZI

This is a conceit one would only expect in a teenage girl's diary.
Or perhaps at the juke joint crying into a beer. The remainder of the
exposition is a sorry example for justifying the cracked paving stones
to an absurd destination.

>Why you choose to engage in such silly diversions away from simple truths is
>interesting.

Simultaneously silly and interesting? Your topic and you are the
first one to take shelter in this veneer of pouts and sulking. I've
laid out the math, complete, you've both acknowledge it, and then
claim it was unknown to you.

It bears re-visiting to wrap this up, but I have no doubt it will make
any impression on your future claims. That is of little concern to me
however as every forum needs a joker in the deck. It keeps stasis
from dominating this as a morgue - and silly is as silly does.
"But at my back I always hear
Times winged chariot hurrying near;
And yonder all before us lie
Deserts of vast eternity."

>You have taken a simple conceptual example to extremes.

Simple concepts have the capacity for resilience and extremes and can
tolerate all such examinations to emerge unscathed. A binary outcome
has no resilience and is remarkably brittle, suffering subtleties with
stress fractures such as you exhibit. Your work, outraged at
examination, simply doesn't measure up to any of these "ideals" you
hide behind.

Tomorrow we continue the brutal examination.

I did, too. But antennas carefully developed and documented for good MF broadcast performance also are useful for 160 meter ham applications.

And as far as significant radiation at elevation angles below 15 degrees, Richard Clark might have allowed for systems operating above 30 MHz, which include several ham bands, I believe. Use of these bands often is line-of-sight between terrestrial endpoints, and would not be very successful if all antennas had low relative fields near the horizon--as implied by Richard Clark's post. FM and TV broadcasting and public service radio (police/fire etc) use such low-angle radiation successfully, and so do ham radio operators.

3215. jaycar uhf aerial problem

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-23 11:28:06 UTC
From: gregB <gbarrell@telstra.com>
Message-ID: <bRpEe.969$TZ.11729@nnrp1.ozemail.com.au>
Source record: 72881

I am in Australia and have just bought
a Jaycar 91 element UHF TV aerial.

It is supposed to cover frequencies from 470 to 862 MHz.
I want to use it for Digital TV reception.

http://www1.jaycar.com.au/productView.asp?ID=LT3182&CATID=31&keywords=&SPECIAL=&form=CAT&ProdCodeOnly=&Keyword1=&Keyword2=&pageNumber=&priceMin=&priceMax=&SUBCATID=478

The aerial is in kit form
and main beam comes in three sections.

The cryptic instruction sheet does not say which way round
the centre of the three sections should go and there are
no indicating marks either.

Depending on which way you have it the spacing of the
elements in the centre section will change in relation to
elements in the other two sections.

Is this a problem?

Is there a way to check for the correct orientation
other than trying it both ways?

Thanks in advance,
Greg.

well, there should be some logical progression from front to back on the antenna. normally the elements get larger as you go from the front to the back of the antenna. if you can't sort it out from the instructions, picture on the web or in the instruction book, then try calling their support line and ask.

My mistake was a semantic one. I didn't know the definition
of "glare" and used the word improperly. I appologized for
that mistake as soon as I realized it. Because of the
incorrect definition, I probably inadvertenly made some
false statements about "glare". If you replace the word
"glare" with "reflections" in all my postings, the claims
are still valid, given the boundary conditions. One semantic
mistake does not overturn the laws of physics.

> Tomorrow we continue the brutal examination.

Since glare (defined properly) has nothing to do with
transmission lines, it is off topic for this thread.
This thread has always been about reflections. My
mistake was in thinking that "glare" and "reflections"
were synonyms.

With all this attention, one might think that someone in his county might hear of this and take a second look at the engineering. It might be true that being in the boonies, nobody really cared at the time when Charlie said he was goin' to put up a tower, But now that it is there, looking like a ride at CB World, they might want to review it. We also need to keep an eye on the SK list. Something could happen to innocent folks if it falls the wrong direction, and in my experience there is no right direction for a tower to fall.

Dave, thanks for the reply.
The spacing does generally increase but not
progressively.
Some intervals are a few centimeters less than the previous one.

Richard Fry wrote:
"Richard Clark might have allowed for systems operating above 30 MHz.,
which include several ham bands, I believe."

I believe so too.

From page 810 of Terman`s 1955 edition:
"Space-wave Propagation. At frequencies above about 30 MHz, the
ionosphere is not able to refract energy to earth, while the ground wave
attenuates to negligible amplitude in a relatively few hundred feet."

On the preceding page, 809, Terman presents Fig. 22-4 which gives among
other things the magnitude of the reflection coefficient for a
vertically polarized wave versus the incident and reflected angle
(symbol = psi, and they are identical). At zero-degrees, the coefficient
is 1.0. It falls to about 0.17 at 10-degrees, which is the minimum or
Pseudo Brewster Angle. From there, it rises to about 0.5 at 20-degrees,
and about 0.7 at 70-degrees incidence. The nip in vertically polarized
radiation does not exist at zero-degrees, the takeoff for ground wave
propagation. The ground wave is interactive with the surface all along
its path.

The space-wave does not depend upon interaction with the earth all along
its path, as the ground wave does. The wave along the earth at 30 MHz
and above "attenuates to negligible amplitude in a relatively few
hundred feet." It depnds upon reflection from the ionosphere or or
something else for popagation beyond the horizon.

Best regards, Richard Harrison, KB5WZI

However this not mean that a direct ray at VHF and above cannot propagate well on a line-of-sight path near the Earth that is tens of miles in length--especially if a Fresnel clearance of 0.7 or better exists for the path. Such service is produced by radiation from the transmit antenna typically at elevation angles from zero to several degrees BELOW the horizontal plane.

If otherwise, the service areas of TV and FM broadcast stations would be very small.

Leon, I just now discovered your request for my data on antenna terminal impedances for various heights above ground. I'm sorry to have missed your request when you asked for it,, so I tried to send the data to the email address shown on your posting. However, the address 'EXDAX143@YAHOO.COM did not work.

If you'll send me your correct email address I'll send you the data you requested.

Walt, W2DU

OK.

It is like this, years ago, in the 1980's, when telnet was still being used on the predecessors of newsgroups, there was no way to logically organize "posts."

Still, into the 90's, most all "news clients" lacked any meaningful way to organize threads and/or posts.

At the end of the 90's a few news clients managed to "get-it-together" and organize threads and posts with pretty good results.

Now it is 2005. Windows xp comes with a completely functional news reader which holds threads and posts in perfect order--no longer do I have to have the text being responded to placed above the text which is being issued in response. Still, many ancient news readers are in use, and the users have not bothered to upgrade them. Also, many are reading these posts from webpages...

That is all their responsibility now, if they are unwilling or unable to setup a decent news reader and come up to speed, that is their problem--there is NO longer a real need to bottom post, indeed, it only slows down ones interaction with the group and places an un-necessary burden to be cutting and pruning text...

... the etiquette and use manuals of usenet need upgrading ...

I will be top posting...

end of story...

John

>have to have the text being responded to placed above the text which
>is being issued in response.

Guess what? You are not the only person that is reading a thread,
and those that are are not all on windows xp. Outlook express is a
dog. It has also been around way longer than XP has.

You assume way too much, and those assumptions have ALWAYS screwed
up someone that doesn't live in your perfect world of "organized
articles".

There are protocols in place for this very reason, and all the logic
you throw at it doesn't change that fact.

> Still, many ancient news readers are in
>use, and the users have not bothered to upgrade them.

That has not a thing to do with the problem. Your opinion about
what is or is not a good news reader has NO bearing on proper
protocol. The problem is that posters such as yourself ASSUME way too
much, and no one else in the world needs to cater to YOUR idea of what
is modern. Again, Outhouse Express is a total dog. That opinion is

held in the eyes of many.

> Also, many are
>reading these posts from webpages...

Another tragic screw up. Especially when they reply from web
access.

>That is all their responsibility now, if they are unwilling or unable
>to setup a decent news reader and come up to speed, that is their
>problem

I find that you are unwilling or to stupid to understand the fact
that not everyone even reads news the way you do. I happen to read
posts chronologically, despite my reader's capacity to show threads in
a grouped manner. That is a choice. Deciding to throw out the
standard accepted decades long protocols based on your opinion of what
is or is not modern is just plain arrogant ignorance.

>--there is NO longer a real need to bottom post, indeed, it
>only slows down ones interaction with the group and places an
>un-necessary burden to be cutting and pruning text...

You are NOT anyone that can declare such a thing.
>
>... the etiquette and use manuals of usenet need upgrading ...

Your brain needs to conform. That is the only upgrade required.

You claim others haven't gotten up to your modern standard and that
is where YOU are wrong. Despite any news reader clients capacity for
sorting articles, it is ALWAYS proper to make the post in a manner
such that a person reading ONLY that post can garner the gist of the
article WITHOUT any requisite to read additional articles. THAT is
the whole point. Not only that, but you idiots invariably quote the
entire article to which you respond, which is another mistake.

>I will be top posting...

You are stupid... You utilization of Outhouse Express proves that
beyond a doubt. I am surprised that you aren't posting in HTML and
defending that as well. What a total ditz you must be.

>end of story...

End of fact finding and declaring mission.

3235. Recommendations for a Vertical

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-23 19:05:16 UTC

Hi All,

I have a Hustler 5BTV that finally bit the dust after 25 years. I had my house painted last year, and the painter's ladder got into an argument with the antenna a few times, and just about destroyed it. I'm looking for something that will do at least 80 thru 10--WARC bands would be nice, and if there is one that also covers 160, that would even be nicer. What do you recommend.

Richard Fry wrote:
"Such service (VHF and above) is produced by radiation from the transmit antenna typically at elevation angles from zero to several degrees BELOW the horizontal plane."

A broadcaster doesn`t want to skip over his station`s nearby customers. His distant customers likely receive the station from a grazing incidence due to earth curvature.

I initially set dishfeeds on point to point microwave systems with a carpenter`s level for the right elevation angle. I seldom was able to improve the signal using on-the-air adjustment of antenna vertical elevations.

In Scotland a few weeks ago I noticed the Satellite dishes aimed at birds parked over the equator. Scotland is so far north that the dishfeeds seemed horizontal. I saw some that dipped below the horizontal. I doubt those were adjusted for best results. The beamwidth is probably enough to get a picture anyway.

The point to point paths we designed had enough clearance to allow anomalous atmospheres making the earth appear half again its actual size. To that grazing point clearance, we added 0.6 1st Fresnel zone clearance.,

Then we produced paths with 40 dB fade margins and limited the paths to 22 miles. Where we could, we produced redundant paths through looped systems or space diversity.

High fade margins help when there are no fades by suppressing system noise, a must in long systems with many hops.

Best regards, Richard Harrison, KB5WZI

OOPS!

Half again normal size? No, 2/3 normal size. It requires taller towers..

Best regards, Richard Harrison, KB5WZI

I've had good luck with my Butternut which I've had for about 15 years. Mine doesn't have the WARC except for 30 meters but you can get one that does do WARC's and even mine can be modified with an aftermarket conversion kit from Butternut. I have had two occasions to order replacement parts (a matching section and a "doornob" capacitor and sevice from Bencher was outstanding...about two days from Chicago area to Maryland.

Mine is ground mounted. Its been good for DXCC, mostly on 40. 80 meter bandwidth is quite narrow though, but I have about 30 countries with it. I think they have another version, a bit taller, which is for 80 and 40 only. I don't remember if they sell 160 coils.

Jon Teske, W3JT

I will probably get flamed badly for this, but, I bought an MFJ-1798A. It covers 2 meters through 80 meters. I use it with both a ts-440 S/AT and a yaesu FT-817. I have gotten great reports from both all the way down to 1/2 watt. Mine is "mounted" on 10 ft of mast in the middle of a small city lot and I love it.

Top posting in a forum for professionals, when one claims to be one,
and the PROTOCOL is NOT to do so, could easily be argued as quite
narrow minded.

The word for today is CONFORMITY.

You conform to standards every day. Many that you have no choice
on. In these forums, just because your lame news reader was written
by a total ditz that gets way more money for his products than he
deserves, doesn't mean that you should just go with your lazy assed
flow. Do you also wear your pants down past your ass, like these
other kids today?

Personally - if you like it and it worked well - I would just rebuild it !
http://www.dxengineering.com/Products.asp?ID=13&SecID=16&DeptID=8

Of course -- it does not work 160 meters and 80 meter has a limited
bandwidth.
http://www.dxengineering.com/Products.asp?ID=34&SecID=16&DeptID=8

It's still made ... gets high marks for a vertical requiring radials.
Hustler 5-BTV assembly manual and parts list

Fred, thanks for the reply.

Yes, the photo does show a longer interval at the
left end and is probably correct.

I think this is helped by the perspective of the photo.
On the ground both orientations look plausible.

Also this assumes it was put together correctly
and not at random buy the advertising department.

I was really hoping there might be a formula for
working out the element spacing.

Regards,
Greg.

Mike Powell wrote:
"Our graph paper was drawn to 4/3 earth radius."

VHF and higher frequencies are generally said to require a line-of-sight path.

Terman writes on page 820 of his 1955 edition:
"For the standard atmosphere, where dM/dh=0.036, the equivalent radius is 4/3=1.33 times the natural radius of the earth.

There are times when the atmosphere doesn`t bend radio waves toward the earth and even bends them away from the earth. If you need to build a high reliability chain of microwave relay stations, you must provide enough path ground clearance so that you`ll have paths when the radio waves bend up as well as when the waves bend down. You pick the excess you can afford for the statistical reliability this excess has been shown to provide. I recall picking k=2/3 actual earth radius. This lead to purchase of this type of graph paper to plot the paths on showing land contours and possible obstructions.

Terman also om page 820, gives formula (22-7b) for:
Radio horizon in miles=aq rt (2h). where h is the height of the antenna in feet. You can approximate many of these in your head.

Best regards, Richard Harrison, KB5WZI

3268. The Failure of Poor Concepts in Discussing Thin Layer Reflections

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-24 06:22:55 UTC
From: Richard Clark <kb7qhc@comcast.net>
Message-ID: <s9b6e1drmf2f30rmqn5fbf6pr302chkihf@4ax.com>
Source record: 72833

We begin with the model found at:
http://www.qsl.net/w5dxp/weblaser.GIF

Which has been variously described in text as:
1w | 1/4WL |
laser-----air-----|---thin-film---|---glass---...
1st medium | 2nd medium | 3rd medium
n=1.0 n=1.2222 n=1.4938
Pfor=1w Pfor=1.0101w Pfor=1w
Pref=0w Pref=0.0101w Pref=0w
which, of course, is in error

Employing what has been described as the cogent math:
Imin = I1 + I2 - 2*SQRT(I1*I2) = 0
or:
Ptot = P1 + P2 + 2*Sqrt(P1*P2)cos(theta)
or:
Ptot = P1 + P2 - 2*SQRT(P1*P2)

However, this math is far in advance of the necessary ground work to first establish I1|P1 and I2|P2 in the first place. It may be noted that they have been "assigned" values. Unfortunately the derivation of those values, lacking reference, are either pure whim and fantasy, or they were found by a formula, as of yet unreported. This will not pass.

The formula either discreetly hidden or completely unknown is a class of optics math called Fresnel's Equations. I will likewise limit their discussion. It requires the computation of the transmission coefficient, and the reflection coefficient both of which are then expressed in the energy equation. When you take the intensity times the area for both the reflected and refracted beams, the total energy flux must equal that in the incident beam. That equation appears as:
(rï¿½ + (tï¿½ ï¿½ n2ï¿½ ï¿½ cos(theta-t) / n1ï¿½ ï¿½ cos(theta-i))) = 1

It stands to reason that this can be quickly reduced without need to use transcendentals for an angle of incidence of 0ï¿½ (which results in a refractive angle of 0ï¿½). All that needs to be known are the coefficients which for that same angle simplify to
r = 0.0999918999... a value that is the limit of an asymptote;
it is also invested with either a + or - sign depending upon the polarization (another issue that was discarded in the original discussion as more unknown than immaterial)
t = 0.9000081000... a value that is the limit of an asymptote;
here, too, there are polarization issues we will discard as before. All this discarding comes only by virtue of squaring:

rï¿½ = 0.00999838....
tï¿½ = 0.81001458....
I presume that the remainder of the math can be agreed to exhibit:
that part of the energy reflected amounts to 0.999838%
or otherwise expressed as:
9.99838mW
and
that part of the energy transmitted amounts to 99.000162%
or otherwise expressed as:
990.00162mW

It follows that at the second boundary there is less power available due to the conservation of power observed at the first boundary. The optics are hardly remarkable at this second boundary as they exhibit nearly the same results, by percentages.

It then further follows that at the second boundary the amount of the original energy passing through the first medium (air) has been reduced to allow for a reflection returning to the first interface of only 9.89841mW. Needless to say, that same first interface is going to conserve energy by the total of refraction and reflection being equal to the energy incident upon it. I will skip that to allow ALL of this second reflection to "try" to totally cancel the first reflection:
9.99838mW - 9.89841mW
or
99.968ï¿½W

Now, admittedly, this appears all quite trivial and a strain on the precision to say the least. However the "initial conditions" have been stated to be an unrealistic example, or a perfect example, or a thought experiment, or... what have you. As a consequence this minute excess of energy stands in contrast to the expressed desire to prove "total" cancellation. I need not remind the reader that this could only get worse in the real world.

But how does this "perfect" result fare in the real world where this 1W laser has an un-cancelled reflection remainder? How does it fare in an application to reduce reflections that the eye is sensitive to? We can presume that to be either 510nM or 555nM, or somewhere in between.

A laser of this power will have a beam size on the order of 1mmï¿½. If you were to shine it against a white target that was exposed to the noon day sun, on the equator, at either equinox, we could compare it to the power of the sun's illumination. In this case, and being quite generous, I typically describe the available power from the sun as being 1000W/Mï¿½. This laser then would, in terms of W/Mï¿½, be quite powerful at 1,000,000W/Mï¿½. This is more than 1000 times more power than the sun's exposure to the same target.

However, the sun does not radiate one wavelength of energy. So, if we were to reduce the amount of sunlight confined to that in the Lased BW at its operating wavelength (noted above); then let's consider that the sun's power is in a BW of 2000nM and we are talking about (and I will be MOST generous to offer an absurdly wide) Lased BW of 20nM. It follows that the Lased power is thus 100,000 times brighter than the sun in the same BW for the same wavelength. But this still neglects that the sun's power is not evenly distributed throughout this 2000nM BW.

I am not going to pencil whip this further. Let's simply return to that un-cancelled power and look at it instead:
99.968ï¿½W
in that same 1mmï¿½, which if we cast to the same terms of comparison to sunlight it becomes 99.968W/Mï¿½ which is a tenth of the power of the sun's total BW emission. But we are talking about brightness, and we do not perceive the total BW of the sun's emission. As you may guess I am going to use the same BW correction to find that the un-cancelled reflection products are
TEN TIMES BRIGHTER THAN THE SUN!

Consider that this is being exceedingly generous (to subdue the brightness of the Laser and its reflections) in contrast to the actuality of even greater brilliance due to narrower BW and the actual power distribution of the sun's energy across its spectrum of emission.

Now, there is every chance I slipped a decimal point here or there in my rushing through the numbers. I will leave that to others to decide and exhibit my mistakes. If they are sufficiently in error, we can revisit the conversions and equivalencies in viewing this un-canceled reflection product. I bet it will still be quite brilliant and not the blackness so prophesied.

Vision is so taken for granted, that few who venture into the field of optics have the discipline to divorce their senses from the numbers at the right time, or the common sense to re-invest sight into what would be observed.

The only assigned value is the one watt into the glass. All
other values are derived by formula. Those formulas are trivial
but I will report them here and now.

I rounded that value to 0.1 which is certainly within engineering
accuracy. The n1 value is actually 1.222222222222... but I thought
four decimal places would be enough. :-)

Since we are dealing with powers, there's no need for a transmission
coefficient. T, the transmittance can be calculated from the power
reflection coefficient, R, the reflectance. The reflectance is:

R = r^2 = (0.1)^2 = 0.01 i.e. 1% of the incident power is reflected.
T = (1-r^2) = 0.99 i.e. 99% of the incident power is transmitted.

I chose the index of refractions to obtain those two values which
are very easy to work with - almost no possibility of mistakes.
(I appologize for under-estimating your ability to make mistakes. :-)

> I presume that the remainder of the math can be agreed to exhibit:
> that part of the energy reflected amounts to 0.999838%

> 9.99838mW
> and
> that part of the energy transmitted amounts to 99.000162%
> or otherwise expressed as:
> 990.00162mW

Richard, you should know better than to use the amplitude reflection
and transmission coefficients on powers. You should be using the power
reflection coefficient, R, which is the reflectance and is the square
of the amplitude reflection coefficient. The power transmission
coefficient, T, is the transmittance and is one minus the reflectance.
Because of that math blunder, your results are incorrect. I am deleting
the rest of your posting for that reason. Please retry your calculations
using r = 0.1, R = 0.01, and T = 0.99

The amplitude reflection coefficient, r, applies to both E-fields
and H-fields, so you have to square it to get the power reflection
coefficient. rho, the transmission line reflection coefficient,
applies to voltage, not power. You have to square rho to obtain
the power reflection coefficient which is rho^2.

So rounding the amplitude reflection coefficient, r, to 0.1 and
squaring it to get the power reflection coefficient, R = 0.01,
we can see that 1% of the power is reflected at each boundary

in the example above. What incident forward power does it take
to get 1w into the glass?

1/.99 = 1.010101 ... watts

That's exactly the forward power in the thin-film in my example.
(There's that formula that you were demanding.)

And since the entire system is assumed to be loss-less, one watt
steady-state is required from the laser. So where does the extra
power come from in the forward power in the thin-film? The
extra 0.010101 ... watts in the thin film is the reflected power
that is 100% reflected due to wave cancellation between the
externally reflected wave and the internally reflected wave.

The external reflection is simply 1w*0.01 = 0.01w
where 0.01 is the power reflection coefficient, R.

The internal reflection is 0.010101w. To obtain the
amount of power transmitted through the first boundary,
multiply by 0.99, the power transmission coefficient.
Thus the interferring wave becomes 0.010101*0.99 = 0.01w

The magnitudes of the external reflection and the internal
transmission are the same. The thin-film being 1/4WL causes
those two reflected wave components to be 180 degrees out
of phase. The two reflected wave components are cancelled.
The energy components in those two waves join the forward
wave in the thin-film. Quoting the Melles-Groit web page.

"In the absence of absorption or scatter, the principle of conservation
of energy indicates all 'lost' reflected intensity will appear as
enhanced intensity in the transmitted beam. The sum of the reflected and
transmitted beam intensities is always equal to the incident intensity.
This important fact has been confirmed experimentally."

I've used the internet since 1985 [DARPA net] and have yet to see the
11th commandment prohibiting top posting or forcing bottom posting.

I prefer TOP POSTING. I've read the original message previously, it is
stored sequentially on my computer sorted by thread and date if I need a
refresher, and I don't have to scroll through a lot of attached garbage
to get to your meaningful or meaningless comments.

TOP POSTING, IMO, provides much more efficient use of my time.

Get a life. There's much more to life than criticizing where a response
is posted.

Indeed, the "governing" RFC even went so far as to
state that bottom posting was the preferred method
of the author but that there was no hard and fast rule
about it.

With top posting, you can quickly "thumb" through the
posts with your hand on the "Next" button. With bottom
posting you have to page down through much already-seen
and over-quoted material. The net result is that bottom-posted
articles tend to get skipped without the new material being read
let alone being visible.

Hello everyone,

I would greatly appreciate any advice in subject of choosing a vertical antenna for satellite operations. I can hear VO-52 / FO-29 5-7 / 5-9 using my mobile antenna NR 770 H fix on a mast 9ft above the ground.

I am cosidering builing a Super J-Pole antenna.
http://www.n7qvc.com/amateur_radio/copper.html

Do you think that this vertical will be sufficient to bounce 50W of signal back to Earth of the satellite ? If not , what other homebrew antenna will be fine for this purpose ?

Thank you for your helpful response .

Phil

Phil

I've been trying to figure out how to build an antenna for receiving polar orbiting weather satellite signals. The satellites send down RHCP on 137 MHz.
A turnstile antenna works pretty well for satellite monitoring, and is pretty easy to build.
There are helical configurations that are commonly considered to be the ultimate weather satellite receiving antenna, but can be tricky to make work properly..
I submit that I know a way to build an antenna with 4 dipoles that perform as well as (or better than) a helix for satellite reception. I refer to the hemispherical patterned antenna concept as the "Cross". It is simple and wouldnt qualify as an invention, its a concept, and it works. It is alot easier for me to build one than it is to describe it. But, the cross antenna is two pairs of crossed dipoles. Each pair is two crossed dipoles spaced apart and fed in phase. One pair is fed 90 degrees later than the other.

I'd be "only too pleased" to E-mail notes and performance data on the concept if you have interest.
I can produce good images from NOAA 17 whenever it is above 1 degree (2 degrees would be a safer number) above the horizon, viewing it from horizon to horizon with that stationary, 4 dipole array.

Jerry

Polymath:

Yep, unless you have all day to start paging though past commented
texts of posts--top posting is where it is at!!!

Some people have been sold the line that there is something leet about
bottom posting--obviously they haven't a clue... but even think they
fool others!

Only reason you should have a problem these days, is if you are still
using telnet to read your news and email!

3292. Balanced vs. Unbalanced Tuner

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-24 18:32:37 UTC
From: greg knapp 5 <gknapp@freshrain.org>
Message-ID: <wtednatQf9NbQ37fRVn-iQ@speakeasy.net>
Source record: 72857

I have decided to erect an 80 meter dipole at 70 feet fed with 450 or 600 ohm open wire, for use on ALL HF bands between 80 and 10 meters. Power output will be 1000W CW and 1200W PEP.
(1) Which is the better setup and why: a Ten Tec 238B unbalanced tuner with a DX Engineering 1:1 balun on antenna side of tuner OR a Palstar BT1500BAL balanced tuner?
(2) Also, if I later decide to erect an inverted L for 160/80, can I use a balanced tuner with a DX Engineering 1:1 balun put on antenna side of tuner, but reversed in direction (converting unbalanced to balanced), or need I get a different tuner?
(3) In a perfect world, I'd buy both tuners (one for balanced and one for unbalanced), but I can't afford it. Also, if I go with the unbalanced tuner, will the balun waste a ton of RF in heat and loss?
(4) I made a similar post on the Ten Tec List, and received lots of advice on point designs, but not the COMPARISON data I was looking for that will help me make the final decision to go with a balanced tuner vs an unbalanced (with balun) tuner.
(5) I have plenty of room, would it make any difference if I put a 160 meter dipole instead?
Thanks & 73,
Greg, N6GK

I use similar antennas, the ladder line is tied directly to coax with
ferrite beads over the coax to act as a choke balun.

When I used a tuner, I simply used the unbalanced input.

If your intention is to take the ladder line all the way to the tuner, go
with a balanced tuner.

I've got plenty of trees to hang up a dipole for 40 meters and feed it with ladder line. Power level =< 100 Watts.
What's the opinion(s) on the wires contacting leaves, especially near the end points? Better to use plastic insulated wire rather than enameled wire?

Phil wrote:
"If not, what other homebrew antenna will be fine for this purpose?"

A turnstile with reflector?

High gain comes from narrow beamwidth. A lower gain antenna is easier to use as it is a larger window on the sky.

Unless the vertical antenna is an axial helix or something similar, it likely has a null in the direction of its open-circuited end. There are better choices.

There are many antenna options. Most are covered in the ARRL Antenna Book. It has a complete chapter on "Antennas hor Space Communications" In my 19th edition, this is Chapter 19. Construction details are given too.

Best regards, Richard Harrison, KB5WZI

Dave <noone@nowhere.com> wrote:

>how does the balanced tuner get from the unbalanced output of the amplifier
>and the balanced feedline? is there not a balun in there somewhere anyway?

I've seen three approaches used:

- Asymmetrical (unbalanced) tuner of the T or L or pi configuration,
with a balun at the output. This seems to be the most common
configuration, but is often said to suffer from a degraded balance
or unacceptable losses in the balun when feeding high-Z loads.
It's not easy for a balun to provide adequate choking reactance
when feeding such loads.

- Tuners which use a symmetrical T or L configuration, with the input
to the matching network being fed from the rig/amplifier's 50-ohm
output via a balun. An internal W2DU-type "ferrite beads on coax"
balun seems to be popular in such designs.

- Link-coupled tuners, such as the Johnson Matchbox and the newer
Z-match designs. The input side of the circuit operates unbalanced
and is usually asymmetrical, while the output side (the link) is
balanced with respect to ground. The input and output sides are
coupled inductively. There's sometimes a small amount of imbalance
created by capacitive coupling across the link, but this seems to
be small enough to have little practical effect on the quality of
the balance. In this case, the balanced-to-unbalanced function is
performed by the inductive link, and there's no separate "balun"
component.

No balun required in a properly designed unbalanced tuner. See the
Johnson Matchbox series.

Hi OM,

You are trying to be too coy about your address. I suspect you think
it will cut down on spam. Truth of the matter is your address is
quite obvious in the headers (shown above your post and in the
salutory line introducing this response) where the spambots look -
they could care less how you munge it up in the body.

By the way, Jerry has spent a lot of effort in working on his design.
Consider it closely.

I use insulated wire. And a long-pole tree trimmer to keep the wires
in the clear. Not that hard to clear a path.

Have not seen any published tests comparing balanced vs. unbalanced
tuners, so any comparisons will probably be theoretical in nature.
Also, instread of the dx engineering balun, you might look at a
w2du-style balun -- see his article at
http://www.w2du.com/Reflection2.html

I havent persued this Cross concept with the intention of identifying "just one way" of building an antenna. I dont mean to imply that my choice was a good one. Maybe I should be more specific. I just havent yet learned enough about how this "hemispherical pattern shaped" works. So far, I've seen that 4 lambda over 2 dipoles can be nested into a slanted vertical array to provide highly elyptical polarization thruout the hemisphere. It is two pairs of crossed dipoles, each pair fed in phase and one pair fed 90 degrees later than the other.
I think the turnstile (with reflectors) has been described in many wer sites. I could send you an accurate sketch of one, but you can surely get better instructions from the Internet. Turnstiles are decent antennas for hemispherical CP coverage and pretty easy to understand and build.
If you are definitely going to build an antenna from which you would appreciate hemispherical elyptically polarized coverage, E-mail me. i can/will help you understand either/both the turnstile and the Cross. I wish I could help you understand the QHA or QFH helix antennas, they work very well. But, I just dont have them figured out.

Jerry

so, no matter how you spell it, unbalanced in, balanced out, somehow the
tuner either has a component called specifically a balun, or combines it
into other parts that also transform impedance... essentially making the
whole tuner one big balun. no matter how its done somewhere between the
amplifier unbalanced output and the balanced wire there is something doing
the balun function.

Cecil:

Wow. Those little "ham rule makers" just move in and start attempting to "regulate" everything.

Damn, I am sure there is a name for that particular mental disorder, not having the correct medical term at my disposal--I resort to just referring to them as "control freaks."

You know, a good regulated power supply is a good thing--a world composed of silly regulations is cumbersome!

Hi Ham Op, did you mean no balun required in a properly designed
"balanced tuner"? Are not the Johnson Series balanced tuners?

I've had three HF dipoles strung thru four trees at my remote location out in the boonies for five years. I use common Home Depot insulated stranded #14 600V THHN wire. I've never had any problems at all at the 100-150W level with the wire including at the ends which are buried in the foilage. I do tape the exposed solder joints at the insulators though. There'a a lot of chatter here and there about trees being quasi-conductors and catching fire etc. which I write it off as mythology.

However I have had major problems with the support ropes. The rope is the 3/16" jacketed UV-resistant Dacron type sold by The Wireman and others for ~13 cents a foot, It's not Home Depot rope, it's supposedly the best available for the purpose.

My experience indicates to me that while the wire is OK in all respects thru trees the ropes have to be replaced every two years. The problem is that tree branches of all sizes are very abrasive and will simply eat thru rope if there's any relative motion between the rope and the branches. Which is unaviodable in windy conditions. As a result I'm seriously considering replacing the rope with the same wire I use for the antennas.

If you are skipping posts in threads which you were at one time
reading, you have some serious skills problems that go far beyond your
simplistic laziness to use more than one clic per post. You have the
mentality of a high school drop-out.

<gknapp@freshrain.org> wrote:

>I have decided to erect an 80 meter dipole at 70 feet fed with 450 or 600
>ohm open wire, for use on ALL HF bands between 80 and 10 meters. Power
>output will be 1000W CW and 1200W PEP.

Is the radiation pattern on all of these bands acceptable/useful?

>(1) Which is the better setup and why: a Ten Tec 238B unbalanced tuner with
>a DX Engineering 1:1 balun on antenna side of tuner OR a Palstar BT1500BAL
>balanced tuner?

Study this before deciding: http://eznec.com/misc/ibalun.txt

Considering the capacitor in the Palstar isn't a balanced design, the
capacitive coupling from it to ground is asymetrical, so I would not
call it a balanced tuner. Also, I don't see anything that looks like
a 1500 W balun in there.

Ten Tec says, "Because there are only two variable components, there
is only one setting of each which will provide a perfect match to a
given load impedance. This unique setting automatically provides the
lowest Q network possible. Low Q means low circulating currents, hence
low loss, and it also provides the widest frequency bandwidth of
operation before retuning is necessary (very useful if you're moving
up and down the SSB portion of the band, for example)..."

They are correct when they say that there is only one setting for a
match, but the L-network Q is set by the load and source Z and is
likewise fixed and totally out of the control of the operator. This
may or may not give the largest operating BW and/or lowest loss.

For example, take a load Z of 5 -j10 at 7 MHz. With capacitor Q =1000
and inductor Q = 250 (good luck with a roller inductor), an L-network
of C = 1364 pF and L =0.568 uH will give SWR = 1.02. The network loss
will be 0.1 dB.

Using the same load Z and component Q, a high-pass-Tee network of Cin
= 1438 pF, L = 0.36 uH and Cout = 3912 pF will give SWR = 1.01 The
network loss will be 0.07 dB.

More parts, lower loss. So much for conventional wisdom. Now this is
a pretty wild load Z, but with certain antenna feedpoint Z and
transmission line lengths and Zo, it's possible. Admittedly, the
differences in insertion loss are negligble but they are different in
the -wrong- direction, thus proving the point.

Of course, try and find a tuner with capacitors of this high a value.

Also, there are some impedances that cannot be matched with either configuration of a low-pass (series inductor) L-network. The same can be said for any other topology, but you should be aware of this.

>(2) Also, if I later decide to erect an inverted L for 160/80, can I use a
>balanced tuner with a DX Engineering 1:1 balun put on antenna side of tuner,
>but reversed in direction (converting unbalanced to balanced), or need I get
>a different tuner?

I wouldn't do this.

>(3) In a perfect world, I'd buy both tuners (one for balanced and one for
>unbalanced), but I can't afford it. Also, if I go with the unbalanced tuner,
>will the balun waste a ton of RF in heat and loss?

Maybe. In my opinion balun loss is no different from line attenuation. Line attenuation is magnified by SWR and I see no reason why balun loss wouldn't be too, particularly since most baluns are constructed from a transmission line.

>(4) I made a similar post on the Ten Tec List, and received lots of advice
>on point designs, but not the COMPARISON data I was looking for that will
>help me make the final decision to go with a balanced tuner vs an unbalanced
>(with balun) tuner.

>(5) I have plenty of room, would it make any difference if I put a 160 meter
>dipole instead?

If you have plenty of room, why limit yourself to one compromise antenna?

>and feel it is our duty to do so or you call us idiots.

No. I call you an idiot because you step into a perfectly normal
forum, and fuck it all up, then claim that you are the norm. You may
be correct in one thing... the population of utterly stupid people in
Usenet is rising, and I'll bet that you do not know which side of the
fence you reside on.

>I too have been here since the DARPA days, and had the third BBS in the US
>behind Ward C. and Bob Blue.

Oh boy. I'd bet that claim to be utter bullshit as well. BBS's
sprouted up all over and there were hundreds of dolts just like you
claiming to be the first or second or third. You are very likely full
of shit due to the fact that your resource for your statistic is
flawed. There were plenty of private BBS's in place that never even
got on your special list. Bullshit proven.

Do you also claim to be one of the first HAMs? I'd bet you don't,
as you know that it would be a foolish claim.

>I chuckle at the little pukes that wasn't even born at the time making rules
>and guidelines...

You know nothing about it. Most folks that put forth the protocols
into the faces of dolts like you are older, and were in fact around.
I was around when it was conceived, even before it was put in place.
I'd be willing to bet you do not even know when that was, regardless
of whether you were alive or not, BBS boy.

>

And I prefer editing and bottom posting. Obviously, if you don't take the time to distill the OP's comments, then you bury your reply under his verbiage. Perhaps one of the best arguments for editing is that you have to think about what's important in the previous post. That allows you to focus your reply.

Another criteria for deciding to top or bottom post is your estimation of the audience. Critical thinkers will want to review the salient points of the discussion, and an edited bottom post gives them the facts in a linear fashion. However, if you think your audience is a bunch of attention-deficient rude boobs, then top posting is indicated. Top posting is ideally suited to replies that consist of "Yeah, me too!"

3340. Re: Balanced vs. Unbalanced Tuner

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-25 00:54:58 UTC
From: greg knapp 5 <gknapp@freshrain.org>
Message-ID: <RfGdnUwXnoT7pXnfRVn-1w@speakeasy.net>
Source record: 72806

I read the article you cited, looked at the QST article on the 238A (noting the size of the 3.5 Kv peak capacitor), and looked at the Palstar webpage at the "inside" shot of the Palstar BT1500BAL (huge capacitor by comparison, rated at 4.5 KV; but noted it had a ferrite input balun) and also read W8JI's comparison of balun loss that showed the difference between the various baluns...with the DX Engineering, coiled coax (20 ft "scrambled"), and 60-foot "solenoid", coming out the lowest loss, and with the DXE one being the lowest...but that was at a LOW SWR!

If I had a low SWR on all bands why would I need a tuner? I know it will be pretty high SWR on some bands, so what then?

I guess that is what MY REAL QUESTION boils down to...although I like the "single resonant" L-type Ten Tec 238 unbalanced tuner (and it would work great with my future inverted L), it needs a balun to match it to the open wire feed. Will the balun, at HIGH SWRs, just burn up my watts in heat and smoke? Versus, a balanced tuner (Johnson, Palstar), which doesn't need a balun (just a small one at input, which is at low SWR and negligible loss), and does not overheat. So what I am wrestling with is which configuration AND WHY:
(1) 238B to DXE 1:1 current balun to open wire
versus
(2) Palstar BT1500BAL to open wire.

As I see it from all the answers I've received, there are people with strong opinions on both sides, that have just given me their conclusion: do x or do y. But what I am still missing is WHY do x or y, and how they bounce off one another.

FOR INSTANCE, WHICH COMBO, (1) OR (2) WILL GIVE THE LOWEST LOSS WHEN FEEDING A BALANCED ANTENNA AT AN 8:1 SWR? HOW MUCH LOWER...LOSS 100 WATTS FOR ONE AND 125 FOR THE OTHER? That is what I don't understand yet.

One gentleman did address my question of whether I could feed an Inverted L (like on 160) with a balanced tuner if I used a balun to change the unbalanced feed from the antenna to a balanced feed connected the output of the balanced tuner, saying don't, but why not? Does this mean that a balanced tuner can NEVER be used for UNbalanced loads through use of a balun?

Another gentleman pointed out that most people just go unbalanced and don't worry about the heat/loss in the balun...or change the length of the feed line slightly (per Cecil's method) until you get a "happy" length the balun can handle, and then buy the most rugged balun you can get to handle the mismatches.

CONCLUSIONS SO FAR: As I see it, the 238B has versatility in that it can do both balanced and unbalanced (with a good external balun instead of its internal voltage balun), but the external balun will heat up and could even fail at 1200 watts to a feed line feeding some mismatched frequencies. But I could lengthen/shorten the balanced feed line to adjust it I guess, looking for its happy spot! On the other hand, the PALSTAR will work great with unbalanced lines (no lossy balun), even at high SWR, but it doesn't do unbalanced lines (although one person mentioned the capacitor might be too small for some situations--but I compared it and it seems to be larger and higher rated (4.5 KV) than the Ten Tec). From your comments I gather that almost any tuner or tuner-balun combo will do great at LOW SWR...but I don't need a tuner for those situations. It's when the SWR gets up higher, like 8:1 or 16:1 that I am concerned about with 1200 watts. In ARRL tests, the Palstar handled that OK, but no such tests for a 238B handling balanced lines (only unbalanced lines a few years back in QST). And what about the DXE, which W8JI tests highly rated, but (if I read the tests right) the tests were done at approx. 1.5 to 1 SWR...no where near the 8 to 1 that I am envisioning. Some of you have said the balun will heat up or even burn up (although I understand the DXE is supposed to be rugged enough to only heat up), but doesn't that rob me of all my power--heat is not a good thing!

And, if both will work, to some degree (barring the burnout of the balun), is the 238B the way to go because I can ALSO do unbalanced lines for other antennas?

I guess if I never wanted to have any unbalanced antennas in the future, I'd go the balanced tuner and be done with it. But if the loss through the 238B and DXE Tuner Balun would not be substantially greater than the Balanced Tuner, but will permit me to match unbalanced lines too for future antennas, then that sure seems the way to go (and adjust the feed line length to best match).

What do you all think?

And thanks for you many replies that have brought me this far so far!

To answer your post:

Yes, I have looked carefully at the theoretical radiation pattern, and it is acceptable for now due to a number of constraints I am working against that do not permit something different.

My goal is to have a strong signal from my QTH out to about 700 miles on 80/75 (for a net for which I am net control), and a decent signal on the rest of the HF bands. I am not so concerned about the peaks and valleys in the radiation patter on the higher HF bands as after 45 years of hamming, my #1 priority is no longer chasing DX pileups or contesting big time...I'd rather spend my time meeting new hams and getting to know them (they are really very interesting people!)...not just "599 CA" or "599 #683 about 600 times in two days. The gain peaks will give me plenty of people to talk with.

I do not forsee having the ability to put up my beam and regular tower up again for various reasons (mainly too much hassel, time, and expense with my poor health), so basically all I have available is one 70 foot high mast (last 30 feet of which are Radio Shack 10 foot sections) in the back sheep pasture, that will have a low angle on the higher bands due to its height that might help make up for no multi-element gain. I do have two multi-band verticals, but the local noise is pretty bad...so hoping going horizontal and perhaps an ANC-1 will provide better receive.

Interesting article. I also read W8JI's article on baluns that discusses this type of balun too. Very interesting. Current balun definitely seems the ONLY way to go!

3348. Short dipole - inductor question

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-25 02:04:39 UTC
From: Ed <Huckleberry_REMOVE_@bigvalley.net>
Message-ID: <Xns969DC20C7B434spectrumhogstarbandn@207.106.93.175>
Source record: 72814

I plan on building a short dipole (inverted V) for traveling in my tiny RV. It will only be designed for 75M. The mast is 20' tall, and I wish the legs to be about 24 feet each.

I still haven't decided where to place the inductors, but in any case, I have a question about their design. This antenna will only be used at the 5 watt level with a FT-817 Yaesu; an LDG Z-11 tuner is also available, but probably not needed.

If I make my 75M dipole legs for about 24 feet long, then I figure I will need about 70 uH inductors if they are center located.

My Question: What would be the requirement for a 70 uH inductor that only needs to work with 5 watts? Do I need open air inductor with spacing between windings, or would a smaller multi wound coil with insulated wire suffice?

Thanks for any opinions on this.

Ed K7AAT

It is a whole lot easier to buy black "550" (parachute) cord. Braided and sheathed, it is great. Have had mine up for over 5 years in the open with no problem. In areas where there was contact with something, i.e., a tower or tree about 3 years is all I can get.

Sportsman's Guide usually has the stuff every couple of issues.

Fred:

I live in california :(

However, I am far enough inland (on the east side of the san andreas fault) where when it does drop in to meet davey jones locker, I will own some ocean front property!!!

Mostly it will be the rich industrial areas which go, and you can darn well bet we will lose San francisco (the gay bay).

Even before the news reports it, the guys back east will be able to know it has happened--just listen for the applause.

John

Some different thoughts on painted rope:

Synthetic fibre ropes are subject to UV attack, but they are also
often subject to chemical attack.

If your rope really is nylon (Polyamide), it is resistant to alkalis
but is sensitive to acid attack. It should not be painted with
anything that will be acidic, or create acidic products in
decomposition.

In most serious rigging applications, any synthetic fibre rope or
sling that was subject to chemical inundation (acid, alkali, solvents,
paints, fuel, oil, contaminated water etc) would be condemned.
Additionally, painting the exterior of a rope probably increases the
risk of rot and mildew internal to the rope.

Over here, a very low cost synthetic fibre laid three stand rope
called "Silver Rope" (flat spin taniklon fibre), white in colour, is
used for marine applications. Not only is it dirt cheap, but it seems
to last on small boat moorings for years. I have had 6mm halyards of
Silver Rope up for over 5 years and there is no significant
degradation. (I wouldn't paint it, it resists mild acids, but is
attacked by alkalis.) (Silver Rope is about the same strength as
natural fibre rope, and about 50% of that of nylon.)

My choice for a synthetic fibre rope for non-structural antenna
rigging would be Silver Rope. It is cheap, it holds knots and splices
well, it is resistant to mild acids (pollution by products), and seems
to give a reasonable service life in UV exposure.

Polypropylene is also resistant to mild acids (and alkalis), but it is
a slippery (greasy) rope that doesn't hold knots or splices as readily
as natural fibre ropes.

Richard, it would be nice if you retracted your hyperbole since
by now you have realized that everything above is correct, given
the previously stated boundary conditions. You have certainly
successfully demonstrated "The Failure of Poor Concepts in
Discussing Thin Layer Reflections".

> I am going to use the same BW correction to find that the un-cancelled
> reflection products are TEN TIMES BRIGHTER THAN THE SUN!

There's a magnitude of difference between the *amplitude* reflection
which you mistakenly used and the *power* reflection coefficient,
which you should have used. You will find that the two reflected waves
are exactly the same magnitude (0.01w) and 180 degrees out of phase and
thus cancel to a magnitude of zero in the direction of the source. As I
said before, the reflections from that thin-film are flat black. The
energy components from the wave cancellation join the forward wave
in the thin film.

P1 = 1w*0.99 = 0.99w
P2 = 0.0101w*0.01 = 0.000101w
P1 + P2 + 2*sqrt(P1*P2) = 0.99w + 0.000101w + 0.02w = 1.0101w

You do not understand what Usenet is then. It isn't a message board
between two folks having a conversation, it IS a place where such
conversations can benefit any and all that read them. The entire
point of proper posting is so that ANY person popping into the group
for a read, can garner the entire idea of a post *without* having to
go find, download, and plow through a number of others to do it. It
has nothing to do with YOUR convenience and everything to do with the
stray "just walked in" reader. Your attitude about the whole thing is
what is asinine, and that alone is what prompted your much deserved
put downs. In other words, you DO have a reduced IQ if you don't even
have the time to read, learn and follow the protocols and expectations
of a forum you happen to think is some "do as you please" thing, when
it is not, by any stretch. Your convenience is not the issue in any
way.

Polypropylene deteriorates rapidly from the UV in sunlight. Here in western Oregon it'll last a couple of years before seriously weakening, but in Denver (mile high and lots of sun) it turns to little more than powder in about six months.

Just about any inductor will withstand the power level, so your tradeoffs are among size, weight, expense, weather resistance, and loss. The higher the inductor Q, the lower the loss. But to get the maximum Q you need a large, air wound inductor that stays dry -- any water between turns of any kind of inductor will spoil the Q. I've made an antenna similar to the one you describe (but half the size, for 40 meters) with reasonably low loss using two large powdered iron cores for loading at the feedpoint. It was conveniently matched by link coupling to the cores which of course you won't be able to do if the loads are away from the feedpoint. If you can tolerate the size and/or weight, the use of multiple conductors -- fanned or parallel --, or (not as good) a single large diameter conductor will reduce the loss two ways. First, it reduces the conductor's I^2*R loss which can become noticeable in a short antenna. Second, it reduces the amount of inductance you need and therefore for a given Q reduces the amount of inductor loss. I think you'll have trouble getting reasonable Q and therefore reasonably low loss from a small, multilayer air wound coil. You're best off with a single layer air core solenoid or, not quite as good but decent if done with care, a single layer winding on a large type 2 or 6 powdered iron core.

Just remember to protect the inductors to keep water from between the turns. Also, remember that just beyond the inductors the impedance is

pretty high, so keep the part of the antenna beyond the inductors, in particular, away from leaves, branches, and the like, especially if they're wet.

==========

What a shocking waste of ammunition! The police officer involved
should be fined with a corresponding deduction from salary.

There will have to be a judicial enquiry. The dead person's family
will sue the London Police for compensation. A report will be issued
in about 18 months time when everybody has forgotten all about it.
The names of the people really responsible for the murder will not be
mentioned of course.

In the meantime, English cricket fixtures and other relics of the
British Empire will continue as usual. But use by Brazilian police of
London policemen as exemplary role models will cease forthwith.

Reg.

3367. Design of a 900 Mhz coaxial antenna for GPRS

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-25 08:00:42 UTC
From: Jonas Lonnroth <someone@microsoft.com>
Message-ID: <K_0Fe.29795$d5.182876@newsb.telia.net>
Source record: 72733

In the late eighties, the first handheld mobile phone from Nokia called CityMan 900 had a quarter length antenna stub. As an option, you could by a longer antenna which I believe was a 1,5 WL coaxial dipole. It was fitted with a SMA connector at the end. Anyhow, this antenna worked fine also at the end of a 52 ohm coaxial cable. I used it on a cheap four meter carbon fibre telescopic fishing rod stuck in the ground for hiking when base stations were still rare in the early days of 900 MHz mobile telephony in the Nordic countries. Signals strengths used to be much better with the fishing rod antenna. Results were also better than using a six element 900 MHz yagi hand held 2 meters up.

Recently, a surveyor told me of the problem he and his collegues have in getting a decent signal for the GPRS connection used to get RTK (real time kinematics) correction signals. Field work is often done in difficult terrain where cellular wave propagation is bad close to the ground. Getting up to four meters using my old fishing rod design could help. Only, I have to reinvent the coaxial antenna. Since the cable is ancored at the top of the rod, it doesn't matter that the coax is pliable. A design that gives additional field strength in the horisontal plane over a quarter wave would be preferable (1,25 or1,5 lambda?)

BTW, Sony-Ericsson phones i.a. have the external antenna connector needed.

I'd use a low loss 52 ohm cable with a FME connector at one end. If we assume that the TX band for european GSM is at 914 MHz, what should be the length of the "unbraided" part of the cable - and should the insulator be stripped off?

Regards

Jonas Lonnroth
ex SM5ACM (in the sixties)

Anyone know the formula (if there is one)for
working out the spacing of the elements
on a UHF TV antenna?

Thanks, Greg

Richard, you laid out the math mistakenly using the amplitude
reflection coefficient instead of the correct power reflection
coefficient. Please lay out the correct math for us using the
power reflection coefficient (which is a magnitude less than
the amplitude reflection coefficient). We will await your new
corrected results.

Reg:

That is a pretty close answer alright. Reverse engineering is a very viable method to produce a good functional antenna!

I have seen charts on optimum spacing between elements, in fractions of a wavelength, charts--plotted against number of elements.

Naturally, since I want one now to show--can't find it, but I think a diligent search will produce one or more such charts on/from the web.

If any kind of UHF TV antenna can be considered, suggest using a corner reflector, which can have gains ranging from around 11 to 14 dBi across the whole UHF TV band, with low SWR. They are also quite easy to build (but a lot easier to buy).

"Antennas For All Applications" 3rd edition (Kraus & Marhefka) discusses these in detail, including its dimensions in terms or wavelength.

3385. Raising a 40m dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-25 18:16:00 UTC
From: Ken Bessler <kg0wx@NOSPAMyahoo.com>
Message-ID: <u%9Fe.19639$Eo.5690@fed1read04>
Source record: 72751

My current antenna is a modified Van Gordon "All Bander".
For reference, the stock antenna is 134' of 14g stranded
bare copper fed with 100' of 450 ohm ladder line. I cut off
half of the ladder line and replaced it with a 12 turn, 5-1/4"
rg58 coil. 20 feet of rg58 goes from the coil into the shack.
I then trimmed the antenna to 7.175 mhz.

The antenna is a flat dipole up 20'. Seems to work OK but
I've got the itch to improve it. The feed point is 12" above
the peak of my roof. I was thinking about installing a 5' tripod
and 2 ten foot masts to elevate the antenna's feed point and
convert it into an inverted V. There will be no need to add to
the feedline.

Ok - now you know the facts - here are the questions:

1) A friend recommended I elevate the feedpoint only to 32'
because (he says) it'll work better at a multiple of a 1/4
wavelength. Is this true?

2) What can I expect in performance improvement at either
32' or 40' off the ground? The house is all wood construction
with an asphalt shingle roof.

Thanks for the help, guys!

> Greg.

Making a decent antenna that works over the very wide bandwidth of the TV UHF band isn't at all trivial. And there's a great big handful of tradeoffs -- gain, front/back ratio, impedance match, physical size, number of elements, sidelobe levels, and bandwidth among them. The UHF TV antennas I've seen are mostly a combination of log periodic, Yagi, and corner reflector types -- something like a few log periodic elements with some parasitic (Yagi) elements and a corner reflector. There *are* some formulas which can be used for pure log periodics and corner reflectors -- you should be able to find them on the web, and a serviceable if not optimum antenna could be made with either or both techniques. You'll have to decide how to best make the tradeoffs for your application. The main difficulty with a corner reflector is making a very broadband driven element.

I imagine that beyond designing a basic log periodic or corner reflector structure, most manufacturers do a bunch of cut and try. These days, I'm sure they use modeling programs for it. I'm also sure that after some years of designing the things, the engineers get a feel for the general effect of certain techniques -- say, how to improve the front/back ratio with the minimal number of added elements. Some of the bigger companies might have developed some optimization software. If they have, it's probably kept as a trade secret.

From: richardharrison@webtv.net
Message-ID: <11036-42E53233-155@storefull-3254.bay.webtv.net>
Source record: 72754

Greg wrote:
"Anyone know the formula (if there is one) for working out the spacing of the elemrnts on a UHF TV antenna?"

It`s a choice, not a formula, because of many tradeoffs.

There are many types of TV antennas For a particular frequency, Kraus shows a Yagi on page 66 of his 3rd edition of "Antennas" which spaces the reflector 1/4-wave behind the driven element, and (4) directors are used ahead of the driven element. Each director is spaced at a distance of WL/pi from its neighbors. This gives 15% bandwidth, plenty for a single TV channel, even for Channel 2 at 50 MHz.

The UHF TV channels extend from about 500 to 800 MHz. 633 MHz would would be the geometric mean frequency. 95 Mhz would be the antenna bandwidth at 633 MHz.

The geometric mean of two numbers is the square root of their product

There are many tradeoffs in TV antenna design. Look at some good book concerning the subject such as "TV and Other Receiving Antennas" by Arnold B. Bailey. Chapter 12 deals with "Practical Aspects of TV Receiving Antennas.

NO...doesn't matter.

At the heights you are talking about on 40m (<40'), the higher
the better.

>2) What can I expect in performance improvement at either
> 32' or 40' off the ground? The house is all wood construction
> with an asphalt shingle roof.

Either will be a big improvement over your current 20', but
two 10' masts might not be stable enough without some guying.

My suggestions:

Buy a used Johnson Matchbox for much less than the Palstar. Even the "low
power" Johnson will take a KW. Or if you have the $, get the Palstar.
Use it with a center-fed/ladder line dipole.

Re the inverted L: you are making it much too hard! Just put up a 160/80
inverted-L and feed it directly with coax. There is no need for a tuner
for this antenna (unless maybe you want to cover both CW and SSB on 80).
A separate 80m element can just be paralleled to the 160 wire, like a
"fan dipole". Put down lots of radials. To match the lower impedance on
160, just use a hairpin coil at the feedpoint.

3392. The Extreme Failure of Poor Concepts in Discussing Thin Layer Reflections

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-25 19:08:19 UTC
From: Richard Clark <kb7qhc@comcast.net>
Message-ID: <eu8ae15jscn528qdpjjsameoqp25v9282m@4ax.com>
Source record: 72757

Now we venture to new materials, and in this case a solar cell,
described in text as:

1w | 1/4WL |
laser-----air-----|---thin-film---|---Germanium---...
1st medium | 2nd medium | 3rd medium
n = 1.0 n = 2 n = 4.04

where the second medium might be Arsenic trisulfide glass or Lanthanum
flint glass.

When you take the intensity times the area for both the reflected and
refracted beams, the total energy flux must equal that in the incident
beam. That equation appears as:
(rï¿½ + (tï¿½ ï¿½ n2ï¿½ ï¿½ cos(theta-t) / n1ï¿½ ï¿½ cos(theta-i))) = 1

It stands to reason that this can be quickly reduced without need to
use transcendentals for an angle of incidence of 0ï¿½ (which results in
a refractive angle of 0ï¿½). All that needs to be known are the
coefficients which for that same angle simplify to
r = 0.667 a value that is the limit of an asymptote;
it is also invested with either a + or - sign depending
upon the polarization (another issue that was discarded
in the original discussion as more unknown than immaterial)
t = 0.667. a value that is the limit of an asymptote;
here, too, there are polarization issues we will discard as
before. All this discarding comes only by virtue of squaring:
rï¿½ = 0.445
tï¿½ = 0.445
I presume that the remainder of the math can be agreed to exhibit:
that part of the energy reflected amounts to 11%
or otherwise expressed as:
110mW
and
that part of the energy transmitted amounts to 89%
or otherwise expressed as:
890mW

It follows that at the second boundary there is less power available
due to the conservation of power observed at the first boundary. They
exhibit these results, by percentages:
that part of the energy reflected amounts to 11%
or otherwise expressed as:
98mW
and
that part of the energy transmitted amounts to 89%

or otherwise expressed as:
792mW

Needless to say, that same first interface is going to conserve energy by the total of refraction and reflection being equal to the energy incident upon it. I will skip that to allow ALL of this second reflection to "try" to totally cancel the first reflection:
110mW - 92mW
or
18mW

But how does this "perfect" result fare in the real world where this 1W laser has an un-cancelled reflection remainder? How does it fare in an application to reduce reflections that the Solar Cell is sensitive to?

A laser of this power will have a beam size on the order of 1mmï¿½. I typically describe the available power from the sun as being 1000W/Mï¿½. This laser then would, in terms of W/Mï¿½, be quite powerful at 1,000,000W/Mï¿½. This is more than 1000 times more power than the sun's exposure to the same target.

However, the sun does not radiate one wavelength of energy. So, if we were to reduce the amount of sunlight confined to that in the Lased BW at its operating wavelength; then let's consider that the sun's power is in a BW of 2000nM and we are talking about (and I will be MOST generous to offer an absurdly wide) Lased BW of 20nM. It follows that the Lased power is thus 100,000 times brighter than the sun in the same BW for the same wavelength. But this still neglects that the sun's power is not evenly distributed throughout this 2000nM BW.

I am not going to pencil whip this further. Let's simply return to that un-cancelled power and look at it instead:
18mW
in that same 1mmï¿½, which if we cast to the same terms of comparison to sunlight it becomes 18000W/Mï¿½ which is 18 TIMES THE POWER OF THE SUN's total BW emission. As you may guess I am going to use the same BW correction to find that the un-cancelled reflection products have 1800 TIMES MORE POWER THAN THE SUN!

Thanks, Roy. Since my antenna will be very portable, with a
collapsable fibreglass mast I can't take much weight, ergo, the need for
small wire, and light weight inductors. However, it appears I would be
better off with feedpoint inductors instead of putting them halfway out
the legs of the dipole. I will plan on doing that, and will look into
using iron core inductors instead of air wound.... if I can keep it light
enough. (the mast sags under any appreciable weight). Thanks again.

"I plan on building a short dipole (inverted V) for traveling in my tiny RV. It will be designed for 75M."

A 70 microhenry, or any inductor, is lossy. Why not make the RV part of a small loop which can be tuned with a low-loss capacitor?

My father-in-law was W1DBM, now SK (born 6-6-6) who did the RV thing and ham radio most of his life. He found his Airstream loop was 15 to 32 dB better than a trailer dipole or whip.

W1DBM`s loop appears in a 1978 ARRL "Antenna Anthology"

My MFJ 989C matches an 80 meter dipole with ladderline on all bands
between 80 and 10. There is no smoke, no heat. With this antenna, I
use the standard balun built into the tuner. Other times, I've used
external chokes, either coiled coax or w2du type baluns. I'd recommend
a standard unbalanced T-circuit type tuner, for as much money as you
can afford. It'll do fine for a whole range of feeds, balanced or
otherwise.

Because one of the very important functions of a TV antenna is to reduce multi-path interference causing fading and ghosting, directionality is essential. The quadrifilar helix I'm familiar with is a normal-mode helix; that is, the maximum radiation or reception is broadside to the helix, and it has an omnidirectional horizontal pattern when the axis is vertical. That would be a poor choice for a TV antenna. You might, though, consider an axial mode helix. That's one which has maximum radiation or reception in the direction of the helix axis. I don't have any direct experience with them, but believe they can be made fairly broadbanded. It might be pretty large and cumbersome, though. You should be able to find design data on the web for an axial mode helix.

Sorry, I don't have the third edition of Kraus yet. Is there really a fairly directional quadrifilar helix in it? In the second edition, the quadrifilar helix is described as a normal mode helix, which is my experience, and the pattern shown in the book of a conventional normal mode helix resembles that of a dipole as it should. Quadrifilar helices are commonly used for GPS receivers, where an omnidirectional pattern is desirable.

By the way, I finally got a copy of Bailey -- I came across a copy the other day at Powell's Technical Bookstore, for $15!

Arrgh! I confused this thread with a recent one asking about UHF TV antennas. My response wasn't at all appropriate to this discussion.

I agree completely with Richard Harrison, a quadrifilar helix is probably a good choice for this application.

I sincerely apologize to Richard and other readers for my carelessness and mistake.

Roy Lewallen, W7EL wrote:
"Because one of the very important functions of TV antennas is to introduce multipath interference causing fading and ghosting, directionality is essential."

Yes indeed! In an urban invironment that is especially important. I`ve fought the battle to suppress ghosting and smearing. But, my signal sources were nearly horizontal and they reflected like billiard balls from every reflective object they encountered. Reflections were often in the horizontal plane same as the incident signal.

I would think that shortly after a satellite makes it above the horizon, the incudent wave`s reflected signals would be headed skyward and be unlikely to cause much trouble at the receiver. The quadrafilar helix pattern appears something like a mushroom.

Roy also wrote:
"Sorry, I don`t have the 3rd edition of Kraus yet."

I only recently got it. Now I think it is unfortunate I didn`t have it on order before it was released. It is crammed with good stuff.

Roy also wrote:
"By the way, I finally got a copy of Bailey ---I came across a copy the other day at Powell`s Technical Bookstore for $15 ! "

Congratulations! Hope you enjoy it as much as I. His catalog pf various antennas is without par. His theory is systematic and concise. He must have been a tremendous asset at Bell Labs.

Best regards, Richard Harrison, KB5WZI

"I confused this thread with a recent one asking about UHF TV antennas."

I understand. My strugle with TV reflections involved antennas atop the corporate headquarters. We had to have a perfect color picture in the executive lounge and there was no cable yet. The founder, chairmman and CEO was proud of his luxury and toys. We had a lot of signal, but too many signals due to other skyscrapers around ours. With sharp enough antennas we were able to clean up the mess. Better a hero than a goat!

I think I was very lucky today. I had typed the previous posting and was about to hit the send button when the electric power failed. I was sure it would mean retyping. However, when power was restored, I wert to the archive and found it in storage. Hooray!

Best regards, Richard Harrison, KB5WZI

I'll have to look that up, but I don't think a loop is a viable
option. For one thing, my trailer is only 17' long body. Plus, there is
no way I can get on the roof of this small trailer without dragging
around a ladder. Also, I expect to want to use this antenna when the
trailer is not available, such as possible tent camping.

Thanks for the input, though.

3415. WTB Cushcraft X940 40m Add On or equivalent

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-26 03:11:42 UTC
From: Rick Frazier <rickf@rickfrazier.com>
Message-ID: <42E5A9F4.A3D21DEE@rickfrazier.com>
Source record: 72680

I've got a Cushcraft X-9 beam that is going back up on the tower in a few months, and am looking for an X940 40 meter dipole add on kit....

Alternately, if nobody has one of these squirreled away, what other options do I have for getting 40 meters on the tower without killing the performance of the X9 beam? I can probably put a 40 meter dipole above the beam if I need to, and would imagine I'd need to run it parallel to the boom of the X-9 to avoid coupling to it... A second coax to feed it wouldn't be out of the question (or a reason to mount a multiport switch I have up there). The rub is that the dipole probably couldn't be much more than 8 feet above the X-9 beam, so I'm not sure what that would do to either the dipole or beam...

Thanks

> upon the polarization (another issue that was discarded
> in the original discussion as more unknown than immaterial)

Uhhhhh Richard, the amplitude reflection coefficient, r, is:

r = (nt-ni)/(nt+ni) = (2-1)/(2+1) = 0.3333 = (4-2)/(4+2)

You are never going to get it right as long as you cannot even
calculate the reflection coefficient.

> r² = 0.445

Wrong again! r^2 = Reflectance, R = (0.3333)^2 = 0.1111
or 11.11%

> t² = 0.445

t^2 doesn't matter. The Transmittance, T = (1-R) = 0.8889
or 88.89%

> I presume that the remainder of the math can be agreed to exhibit:
> that part of the energy reflected amounts to 11%
> or otherwise expressed as:
> 110mW

That's correct but doesn't agree with your r^2 value. Let's say
11.11% or 111.1mW for four digit accuracy.

> and
> that part of the energy transmitted amounts to 89%
> or otherwise expressed as:
> 890mW

Let's say 88.89% or 888.9mW for four digit accuracy.

> It follows that at the second boundary there is less power available

> exhibit these results, by percentages:
> that part of the energy reflected amounts to 11%
> or otherwise expressed as:
> 98mW
> and
> that part of the energy transmitted amounts to 89%
> or otherwise expressed as:
> 792mW

You are ignoring the wave cancellation energy and getting the
wrong answers. You have proved my point better than I ever could
have.

The first internal reflection is 888.9mW*0.1111 = 98.76mW. When
that first internal reflection encounters Medium 1, 87.78mW will
be transmitted through to Medium 1. It is 180 degrees out of phase
with the first internal reflection so the two waves will start to
cancel. Thus 2*87.78 = 175.56mW will join the forward wave in

Medium 2. Even after this first re-reflection event, the forward
power in Medium 2 will be 1064.5mW on its way to 1125mW during
steady-state. It is readily apparent that you simply don't know
how to perform this analysis either during the transient state
or steady-state.

The steady-state values are easily known and yours are wrong. Have
you never solved a problem like this before?

> Needless to say, that same first interface is going to conserve energy
> by the total of refraction and reflection being equal to the energy
> incident upon it. I will skip that to allow ALL of this second
> reflection to "try" to totally cancel the first reflection:
> 110mW - 92mW
> or
> 18mW

You calculations are once again wrong. When you add up all the infinite

number of reflections and re-reflections, you will find that the sum of

all the internal transmissions into Medium 1 indeed does equal 111.1mw
thus totally canceling all of the reflections. Assuming a lossless
system, there will be one watt delivered into medium 3. The incident
power necessary for that event is 1w/0.8889 = 1.125w. All reflections
from the thin-film are canceled. Here are all the steady-state powers
calculated for you:

> 1w | 1/4WL |
> laser-----air-----|---thin-film---|---Germanium---...
> 1st medium | 2nd medium | 3rd medium
> n = 1.0 n = 2.0 n = 4.0
Pfor=1w Pfor=1.125w Pfor=1w
Pref=0w Pref=0.125w Pref=0w

Note that T*Pref2 = 0.8889*0.125 = 111.1mW, exactly the amount of
energy required to cancel the initial external reflection of 111.1mW.

In the 2nd medium, P1=888.9mW, P2=Pref2*R = 125mW*0.1111 = 13.89mW
P1 + P2 + 2*sqrt(P1*P2) = 888.9 + 13.89 + 222.2 = 1125mW

Hecht's equations are correct after all. What you have proven is that
when
you ignore the interference energy, you will get the wrong answer.

Source record: 72683

However, it appears I would be
better off with feedpoint inductors instead of putting them halfway out
the legs of the dipole.

Myself, I would prefer them out at 1/2 or even 2/3 from the center.
Better current distribution. What will the antenna be made from?
Wire, or metal tubing? Regular solenoid coils can be made from
any light plastic tube, using light wire. I use insulated wire to act
as a spacer. I then cover them with shrink wrap, or tape.
If the antenna is hard to match to coax, you can use a third coil
at the feedpoint, and tap it for the best match.
If the antenna was tubing, I would use wooden dowel that would
fit in between a section of metal tubing, and wind the coils on those.
I'd weatherproof those some way also.
When I make small loaded dipoles, I think exactly the same way as
I would designing a mobile whip. I'd make the most efficient design
of a 24 ft whip, IE: coil placement, etc, and just double it for a
dipole.
Whats best for a short whip, will also be best for a short dipole
of the same size per leg. The very best location is probably at
the 2/3 to 3/4 mark, but it's not that critical. Even 1/2 out is good.
Reg's vertload can model all that, and tell you the best place, coil
info, etc, etc... In comparing to the real world, it's close nuff for
gov
work. If the apex was high, even a center load could be ok, but if
you only have 5 watts, I would go for every last scrap of efficiency
in the design. Actually, I'd also carry a spare 120 ft of wire to use
as
a full size dipole in the off chance the location could support it. :/
Many would, if they have trees to hang wires from, etc.. Even if the
full dipole is perverted, and making turns, a "Z",etc, it will usually
outdo
the loaded antenna for 75m.

This is it ! http://members.aol.com/k5oe/ The Eggbeater2 guys, I think ?

. After reading Gerald's information on how to construct this antenna I was left unclear about the dimensions table and all the digits shown there.

1) What do they stand for, and how to apply them in the construcion of the antenna ?

And another thing:

Is there any spacing between the loops when they cross eachother on top and on the bottom ?

How about the reflectors, they must be spaced out if they cross eachother inside the boom ? How much is the space ?

Thank you very much again.

Phil

Just a note:

With a link-coupled tuner you can use either a balanced line (ladder line, tv twin-lead) fed antenna or a coax fed antenna. It handles either equally well.

Used Johnson Matchboxes are still fairly common on ebay in the $100 price range. I use mine for all bands 80-10. If you want to roll your own link coupled tuner see:

Here's another war story. Many Chicago TV stations moved to the new Hancock Bldg to use one of the RCA antennas that were stacked there on two masts. When one of the big network O&O stations flipped the switch to start using this new site, the on-air picture at their studio turned to absolute garbage, right in front of all the executive staff gathered in a boardroom to celebrate. The studio was located about four blocks from the Hancock Bldg, and close to the null in the elevation pattern of the new 2-bay antenna they had switched to. Most of the RF they could pick up was from reflections. I think they finally installed a very high gain antenna skewed upward up at a large elevation angle focused at the top of the Hancock Bldg, but the best picture they got was never very good.

RF (RCA field supervisor during the installation
and commissioning of the TV antenna systems)

Richard, if you follow the leads of other gurus on this newsgroup,
you will 'ploink' me, never admit a mistake, and dupe yourself
into believing that you were right all along. Your "Extreme Failures
of Poor Concepts" could have been avoided if you guys had just read and

understood the following two quotes that I have posted multiple times.
What is it about, "... all 'lost' reflected intensity will appear as
enhanced intensity in the transmitted beam.", that you guys don't
understand?

www.mellesgriot.com/products/optics/oc_2_1.htm

"Clearly, if the wavelength of the incident light and the thickness
of the film are such that a phase difference exists between reflections

of p, then reflected wavefronts interfere destructively, and overall
reflected intensity is a minimum. If the two reflections are of equal
amplitude, then this amplitude (and hence intensity) minimum will be
zero."

"In the absence of absorption or scatter, the principle of conservation

of energy indicates all 'lost' reflected intensity will appear as
enhanced intensity in the transmitted beam. The sum of the reflected
and
transmitted beam intensities is always equal to the incident intensity.

This important fact has been confirmed experimentally."

http://micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index
.html

"... when two waves of equal amplitude and wavelength that are 180-
degrees out of phase with each other meet, they are not actually
annihilated. All of the photon energy present in these waves must
somehow be recovered or redistributed in a new direction, according to
the law of energy conservation ... Instead, upon meeting, the photons

are redistributed to regions that permit constructive interference, so
the effect should be considered as a redistribution of light waves and
photon energy rather than the spontaneous construction or destruction
of light."

Well, that is just a different system than I am used to.

Take books for example, when getting a new ones, in a series, I hardly ever re-read the old one just to get a start on the new one. Magazines work the same for me, I never re-read the june issue, when first getting the july issue, just to get a proper start on this new issue.

Or, take emptying the garbage as another example. I hardly ever set the old bag in front of the new one, so that once again I will be forced to deal with the old bag before I can empty the new.

But hey, what do I know?

All I do know is I am NOT responsible for formatting others text, they can do that themselves...

> 1w | 1/4WL |
> laser-----air-----|---thin-film---|---Germanium---...
> 1st medium | 2nd medium | 3rd medium
> n = 1.0 A n = 2 B n = 4.04

I have added points 'A' and 'B' to Richard's diagram.

Let's make the math simple by having the index of refraction,
n, of the 3rd medium be equal to 4.0. The power reflection
coefficient is 0.1111 and the power transmission coefficient
is 0.8889. All powers will be stated in mW.

Since n2 = sqrt(n1*n4), the system will be reflectionless
in the 1st medium. Proof of that assertion will be left
to the reader but that is a necessary and sufficient
condition for a lossless system.

Here is the transient state of the system an instant
after the first internal reflection from point B arrives
back at point A.

```
1st medium 2nd medium 3rd medium
A B
1000mW-->--| |
|-->--888.9mW-->--|
111.1mW--<--| |-->--790.1mW
|--<--98.76mW--<--|
87.79mW--<--| |
|-->--10.97mW
```

Since the 2nd medium is 1/4WL, in the 1st medium, the
111.1mW external reflection will be 180 degrees out
of phase with the 87.79mW internal transmission leaving
very little of the external reflection uncanceled. A
quick calculation indicates 1.37mW left uncanceled.

When the second internal reflection from point B
arrives back at point A, more wave cancellation
will occur. After very few iterations of reflections,
the 111.1mW external reflection will be canceled.
As in the earlier example, the result is flat black

for reflections in the 1st medium.

Richard Clark sez:
> As you may guess I am going to use the same BW
> correction to find that the un-cancelled reflection products have
> 1800 TIMES MORE POWER THAN THE SUN!

1800 TIMES MORE POWER THAN THE SUN from flat black????
Quick, Richard, get a patent on that process.

Someone sent me an email wondering if Richard C. has a death
wish. :-)

Dear Cec, a long time ago I found a copy of "The Hunchback of Notre Dame" in my hands. Translated from the French.

I think I had to catch a train. At any rate I didn't have a lot of time to spare.

So I read the last few sentences in the book. I was immediately fascinated.

I then speed-read the last chapter which was all I had time for.

I made a mental note to read the rest of it should the occasion arise.

Some years later, by chance, in a strange town, with nothing better to do, I called in a cinema. The film was Charles Laughton as the Hunchback on the pillory pleading to the crowd for water. The gipsy girl gave him a flask

I then obtained the book via my local Carneague public library and read the whole thing at a single sitting.

They don't write beautiful books like that anymore. Books which read just as well either forwards of backwards.

The Carneague library, a present to my home town from the generous USA before I was born, still stands and still much used, amidst the old Victorian, soot-darkened houses in the Black Country where it all began.

By the way, I'm on "Vin de Table de France" this evening.

Reg.

It is a text forum?

Well, ya, if attachments are NOT allowed, you have to use uuencode and uudecode to send binary data!!! (and include it IN the message text)

Well duh!

If you need a tutorial on how to use uuencode, I can furnish you with one--the only reason you do NOT see it here is that, I suspect, most are ignorant to how it is used.

Cecil:

Most joking aside, you seen uuencode/uudecode in heavy use up until 1995 when the sudden flood of cheap computers brought all the "riff-raff-know-it-all-regulators" here, since then it tapered until you only see it in use on "binary mostly" chans...

You are correct that in this system (1/4-wave matching layer), the
total reflectance goes to zero.

However, your understanding of superposition is wrong. You
CANNOT superimpose POWERS, or even talk about the "power" of various
reflections in the same media. You can only add the wave amplitudes
(electric fields). THEN you take the total amplitude and square that
to get the power.

but of course ground isn't ground. there is no such thing as ground, or a ground potential, or a perfect ground, or anything like that. and yes, currents flowing in the ground can be a bad thing, but only if you don't understand them and design to handle them.

Cec, I am not aware of what Jacques might have said about English cod and chips. Everybody to his own tastes.

But I do object to the USA tendency to confuse politics with diet, to mix up CIA invented non-existent weapons of mass destruction, and oil wells and pipelines with frogs legs and snails.

French politicians have weighed up the present international situation very accurately and honestly. And acted, not always in accordance with their own interests, but everybody's.

After all, in 1793, they were the first of the true revolutionaries. Vive La France! And, of course, their wine.

Reg.

Hi Tor,

This is all taken care of in the equation for energy conservation that
I posted. The solution is valid barring a simple error of subtraction
that should read:
110mW - 98mW
or
12mW
in that same 1mmï¿½, which if we cast to the same terms of comparison to
sunlight it becomes 18000W/Mï¿½ which is 18 TIMES THE POWER OF THE SUN's
total BW emission. As you may guess I am going to use the same BW
correction to find that the un-cancelled reflection products have
1200 TIMES MORE POWER THAN THE SUN!

All should note that if you have only 98mW (expressed in the correct
terms of course as the area terms have been abandoned) available to
offset 110mW (again with the same proviso) then it stands that Total
Cancellation is always impossible. As the two energy levels are not
equal, there is no other answer.

This is not to confuse the solution with the practical reduction. On
the other hand, when the remaining reflection products contains so
much more power than the sun's exposure, it is doubly amusing to see
it expressed as "0."

Hi !

I want to put up a 40m dipole antenna and my question is what a transmission line to use, I have two defferent type of twin lead to choose from, one is 75 ohm and a TV 300 ohm line. I'm using Yeasu 747 GX and MFJ 949 E for equiment. Thanks

Not sure which indices you are now referring to: n_3=4.0 or 4.04? With 4.0, there is zero reflected light. With 4.04 there is a small amount.

> However, your understanding of superposition is wrong.

Powers obey the equation P1 + P2 + 2*(P1*P2)cos(theta)
when the fields are superposed. 2*(P1*P2)cos(theta) is
known as the "interference" term. That interference term
automatically adjusts the power equation IN ORDER TO AVOID
SUPERPOSITION OF POWERS. That's what I did.

> You CANNOT superimpose POWERS,

I would not even dream of superposing powers. Perhaps you
don't understand the role of the interference term in the
power equation which is to AVOID the superposition of
powers.

P1 + P2 would be superposing powers. I didn't do that.

P1 + P2 + 2*sqrt(P1*P2)cos(theta) is NOT superposing powers.

> or even talk about the "power" of various
> reflections in the same media. You can only add the wave amplitudes
> (electric fields). THEN you take the total amplitude and square that
> to get the power.

Eugene Hecht would be surprised to hear you say such since he
talked about the powers (irradiance) of various reflections in
the same media.

I did not superpose powers. I used Hecht's equations for powers
(irradiance). When E-field1 is superposed with E-field2, powers
obey the equation:

Ptotal = P1 + P2 + 2*sqrt(P1*P2)cos(theta)

where (theta) is the angle between the E-fields, P1 is the power
associated with E-field1, and P2 is the power associated with
E-field2. Reference: _Optics_, by Hecht, equation 9.14

Since the above is a steady-state matched situation, the forward
power in second medium involves total constructive interference:

So Ptotal = P1 + P2 + 2*sqrt(P1*P2)

where P1 = Pfor1*T and P2 = Pref2*R
T is the Transmittance and R is the reflectance
These are very similar to the S-parameter power equations.

Reference "total constructive interference" in _Optics_, by Hecht
equation 9.15. The only difference in irradiance and power is
the unit-area which, for our example, is arbitrary.

Use the 300 ohm line and make it about 62 ft. long,
i.e. 1/2WL.

It depends on how you intend to use your antenna and how long will be the feedline to the shack. You will be concerned mainly with the inevitable loss in the line.

I assume one of your equipments is a tuner.

If you intend to use only the 40 meter band and the length of line is not very long then the best choice is the 75 ohm twin line. It makes a fairly good impedance match with both the antenna and the tuner/transmitter at that frequency. A choke balun can be fitted between the line and the tuner.

But if your line is a long one, then the 300 ohm line will probably be better. It depends on how flimsy it is. Again use a choke balun and a tuner.

If you intend to work on several bands then the 300 ohm line is a must. There will be fairly high standing waves on the line at whatever frequency you are on but losses may not be excessive due to the fairly high line impedance. With 300 ohms it could be higher.

Ideally, for multiband working and a long line you should have a substantial 450 ohm ladderline or, best of all, a 600 ohm open wire line.

But don't neglect the antenna. The best antenna is the highest possible.

Reg, G4FGQ

Hi Tor,

It doesn't matter one iota. You can attempt to achieve a perfect
1:2:4 correlation, or any similar relationship that satisfies the
square laws so demanded.

The point of the matter is with such design characteristics fulfilled,
then each interface reflects/transmits in the same proportion. With
each reflecting/transmitting in the same proportion, the second
interface, by the actions of the first, must have less incident upon
it. It then follows that the same proportion of less incident is not
enough to "Totally Cancel" the first interface reflection.

Observing the conservation of energy at the first interface:
X = 0.89X + 0.11X
Observing the conservation of energy at the second interface:
0.89X = 0.792X + 0.098X

0.098X <> 0.11X

What is even more obvious is that following the second interface, you
have lost roughly 20% of that incident upon the first interface.

There is not enough energy at the second interface, reflected back, to
"Totally Cancel" the energy in the reflection of the first interface.
There can be no other outcome.

That difference yields first interface reflection products that have:
1200 TIMES MORE POWER THAN THE SUN!

Then don't draw diagrams like above labeled with powers of
multiple reflections bouncing around in the same media :)

>Eugene Hecht would be surprised to hear you say such since he
>talked about the powers (irradiance) of various reflections in
>the same media.

Only when dealing with the interference of TWO waves.
He works with electric field when discussing anti-reflection
layers. See 9.7.1

I'm not saying the power equation you give is wrong, but it
is correct for just two waves. With more than two waves, it
obviously becomes more complicated

> It doesn't matter one iota.

Of course it matters. The 1,2,4 combination meets the necessary and
sufficient conditions for the elimination of reflections in medium 1
assuming a steady-state lossless system, i.e. perfectly matched.

> The point of the matter is with such design characteristics fulfilled,
> then each interface reflects/transmits in the same proportion. With
> each reflecting/transmitting in the same proportion, the second
> interface, by the actions of the first, must have less incident upon
> it.

That is simply not true, Richard. You obviously have not read my
Melles-Griot web posting and/or simply don't understand it. The
forward power in medium 2 is greater than the forward power in
either medium 1 or medium 3. You keep making that same mistake
over and over and over. Why don't you simply take time to
understand the truth?

> What is even more obvious is that following the second interface, you
> have lost roughly 20% of that incident upon the first interface.

But you have gained the energy involved in the wave cancellation
in medium 1. The forward power in medium 2 is higher than it is
in medium 1. You don't actually believe the BS by some gurus on
this newsgroup that standing waves don't contain any energy, do you?

> There is not enough energy at the second interface, reflected back, to
> "Totally Cancel" the energy in the reflection of the first interface.
> There can be no other outcome.

Only in your mind, Richard, only in your mind. The outcome in reality
is complete cancellation of the reflections in medium 1 assuming
1,2,4 indices of refraction.

> That difference yields first interface reflection products that have:
> 1200 TIMES MORE POWER THAN THE SUN!

Somebody get the net!

You are assuming the French actually wanted to host the games. I suspect
they have spotted it wasn't going to make money and wanted out.

I suspect our hosting the games is going to cost the UK big time.

Ah but you must avoid upsetting GOD (oops I mean Richard.). A simple answer about grounding given to a guy a while back put him into apoplectic fits, necessitating the doubling of his meds. You see, "ground" ISN'T "ground". That isn't "clever" enough for Richard. He promptly claimed that rf currents flowing in a ground system were a "bad thing' and proceeded to "explain" it all to us. I wish my elmer 30 years ago had been as "clever" as Richard. All these books on the shelves simply are irrelevant, because nothing can be simple, you see... It must be complicated, even if it IS wrong........

>
> P1 + P2 + 2*sqrt(P1*P2)cos(theta) is NOT superposing powers.

You do understand that interference is the result of the superposition of waves traveling in the same direction, right?

> Eugene Hecht would be surprised to hear you say such since he
> talked about the powers (irradiance) of various reflections in
> the same media.

Again Cecil, you're really in no position to speak on his behalf. He might not think that highly of your doing so in fact. Perhaps you should obtain his permission first.

> I did not superpose powers. I used Hecht's equations for powers
> (irradiance).

Actually, the fact that those equations appear in his book (as well as just about any other optics book) does not convey any rights of ownership or invention to the author. They were around a long time before Dr. Hecht.

> The only difference in irradiance and power is
> the unit-area which, for our example, is arbitrary.

You should show him your equation with all the power terms (P1-P4) in it! You had some of the powers going one way, and the others going the other way. You needed them all to add up to some particular number, so you just added them. - or maybe subtracted some of them. I don't recall exactly.

> layers. See 9.7.1
>
> I'm not saying the power equation you give is wrong, but it
> is correct for just two waves. With more than two waves, it
> obviously becomes more complicated

medium 1 medium 2 medium 3
A B
1000mW-->--| |
|-->--888.9mW-->--|
111.1mW--<--| |-->--790.1mW
|--<--98.76mW--<--|
87.79mW--<--| |
|-->--10.97mW

I appologize if the diagram wasn't clear. It is extremely
difficult to draw graphics in ASCII.

But I only ever deal with TWO waves. Above in medium 1,
the two waves are the 111.1 wave and the 87.79 wave.
There are only TWO rearward-traveling waves there. Hecht's
irradiance equation works for those TWO waves.

The TWO waves in medium 2 are the 888.9 wave and the
10.97 wave. There are only TWO forward-traveling waves
there. Hecht's irradiance equation works for those
TWO waves.

Since I am not trying to calculate the power in the standing
waves, there are only ever TWO values of power to deal with.

Sorry for the confusion.

<snip>

Well, it's up guys! The apex is about 40' and the ends are 28'.
Comparing it to my other antennas I'm seeing about a 1-1/2 to
2 S unit improvement on 40m and more on the higher bands.

I did a SWR plot before and after changing it and here's the
sticking point: Before, I had a 2:1 range from 6.900-7.280 and
now I've got 7.000-7.300 but the minimum SWR went from
1.10:1 to 1.55:1. My Elecraft KAT2 autotuner handles that very
easily but I'm wondering what would happen if I added 12 feet
to my 50' of 450 ohm ladder line? Would the minimum SWR
get better or just move? Or both? Does it really matter? (I don't
think it matters based on what I've read here).

Many do this and don't worry about it. I have not heard of anyone hurting a
receiver. I would, however, keep the antennas as far apart as possible.

One thing. The APRS transmitter should be kept as low as possible and still
get the desired results.

You can also sign up to the tapr list and query the Gurus.

Jim Kelley wrote:
> You do understand that interference is the result of the superposition
> of waves traveling in the same direction, right?

Of course, there are two superposition terms in each direction
represented by the two S-parameter equations.

b1 = s11*a1 + s12*a2 toward the source

b2 = s21*a1 + s22*a2 toward the load

The two terms in the first equation interfere with each other
toward the source. The two terms in the second equation interfere
with each other toward the load. When b1=0, the system is matched,
and total destructive interference exists toward the source. In
that case, total constructive interference exists toward the load.

> Actually, the fact that those equations appear in his book (as well as
> just about any other optics book) does not convey any rights of
> ownership or invention to the author. They were around a long time
> before Dr. Hecht.

Didn't mean to imply that he owns them. "Hecht's equations" simply
means they appear in his book. They were around a long time before
anyone on this newsgroup called them "gobblegook". The interference
equations also appear in Chipman's 1968 "Transmission Lines".

> You should show him your equation with all the power terms (P1-P4) in
> it! You had some of the powers going one way, and the others going the
> other way.

Nope, you are confused. All powers are going the same direction for any
individual equation in my article. Destructive interference energy in one
direction equals constructive interference energy in the opposite direction.
If you will wade through the transient buildup to steady-state of the recent
examples, you won't be confused anymore by direction. During the transient
buildup phase, when the first destructive interference occurs toward the source,
an equal amount of constructive interference energy flows toward the load -
same energy, just flowing in the opposite direction. If destructive
interference energy in one direction equals P3+P4, constructive interference
energy in the opposite direction equals P3+P4 to satisfy the conservation
of energy principle.

Perhaps you are remembering the equation (Pload = Pfor - Pref) where Pfor
and Pref are flowing in different directions. But that equation doesn't
appear in my article.

Glad to hear it worked out okay and thanks for the update. Over 1.5 months
is a long time to wait so I probably would've been concerned as well.

FYI - sending a Postal Money order isn't as helpful as one may think. I got
took on a transaction involving a USPS money order sent through US Mail. I
turned it over to the US Postal Inspectors and waited about two months just
to get a letter saying they've referred it to a third-party organization
(Fraud Busters) that did absolutely nothing. The USPS Inspectors are a
joke. You'd be better off relying on eBay / PayPal / MC/VISA for some type
of buyer protection.

No. There are some French and possibily other country's dishes on
the menu, but it's most certainly not even the tinyest bit a French
or Italian Resturant.

http://www.fatduck.co.uk/

The tasting menu is unique to The Fat Duck/Heston Blumenthal AFAIK.

"(... cuisine of the other British nations!)"

Now that is a total destruction of the English Language!!

Let's parse that a bit ...

cuisine ... commonly understood as French style cooking.

British nations ... commonly understood as Canada, or Australia, or New Zealand, or Northern Ireland, or ... Britain, or ....

CONCLUSION: French style cooking of world wide english speaking nations.

Thank goodness he did not say Chinese Cuisine! Would that be Chinese style French cooking or French style Chinese cooking? Ah ha! I'll have Mandarin Duck over a French wine sauce flavored pork fried rice.

SWR has nothing to do with the length of line [assuming low loss line].
SWR is determined solely by the antenna to transmission line impedance.
[e.g. an antenna input impedance of 70 ohms and a 50 ohm cable has a SWR
of 1.4:1 ALL the time].

SWR changes as a function of antenna height above ground because of ground effects. Don't worry about it! The ground effect has a mutual impedance impact on the antenna. Antennas close to ground, < 1/4 wavelength, tend to have lower feedpoint impedances. Antennas > 1/4 wavelength high will exhibit a higher impedance that will oscillate and converge on Ro as a function of higher height, ultimately achieving Ro in free space.

It doesn't matter in the amateur radio world or the engineering world. Physicists will want to understand all the variables involved in the interest of science. That's great! But, I'm more into amateur radio and not physics.

>SWR has nothing to do with the length of line [assuming low loss line].

True in one respect, but not necessarily a complete answer in this
case (I think).

>SWR is determined solely by the antenna to transmission line impedance.
>[e.g. an antenna input impedance of 70 ohms and a 50 ohm cable has a SWR
>of 1.4:1 ALL the time].

True, but that's not the whole story here.

If I understand the OP's setup properly, he's trimmed his antenna wire
down to be a half-wave 40-meter dipole. He's then feeding it with a
combination of ladder line, a coaxial balun, and coax to the shack.

If that's a true picture of the situation, then I would expect the SWR
at the shack end of the coax to vary quite a lot as the length of the
ladder line is changed.

Reasoning: the antenna's feedpoint impedance wouldn't be too far from
the 50-to-70 ohm range, give its resonant length and its height above
ground. This impedance will be transformed by the 450-ohm ladder
line, and the impedance at the ladder-line/coax joining point will
depend on the degree of transformation.

If the ladder line is cut to be an integral number of electrical
half-wavelengths, it would mirror the antenna feedpoint impedance to
the coax. There's be a good match, the SWR on the coax would be
somewhere between 1:1 and 1.5:1, and the rig would quite possibly be
happy without even needing its internal ATU. This is Good.

On the other hand, if the ladder line is an odd number of
quarter-wavelengths, it would transform the antenna's feedpoint
impedance up to a much higher value (in excess of 1000 ohms). This
would result in a severe mismatch at the ladder-line/coax joining
point, and a high SWR on the coax. I'd expect both high losses, and a

significant amount of RF appearing on the coax braid (the coiled-coax choke balun wouldn't have enough choking reactance). The rig's ATU might not be able to match this load at all. This would be Bad.

In these two extreme cases, the SWR on the ladder line would be high, and wouldn't change appreciably as the ladder-line length was changed. Losses in the ladder line should be minimal.

The SWR on the coax section, and the impedance presented to the rig, would vary anywhere from "utterly benign" to "nasty and unacceptable" depending on the length of the ladder line.

The same basic reasoning would seem to apply, I think, for any antenna feedpoint impedance other than one which matches that of the ladder line. Although changing the ladder-line length won't affect the SWR on the ladder line, it can affect the SWR on the coax section (possibly by a lot!) due to the varying transformation of the antenna's feedpoint impedance.

This is, in a way, the converse of Cecil's "no tuner" matching arrangment, which uses a tuned ladder-line feeder to transform a dipole's feedpoint impedance down to 50 ohms on multiple bands by adjusting the feeder length.

It is comforting to note that the ancient ones were wrong about some
things. It may not happen daily, but it happens a lot at 6 meters,
often at 2 meters, and sometimes even higher.

label the frequency determining elements?

Why the xtal and any associated coil or cap used to "pull" the freq in the cmos oscillator... or the pin you take the signal out of on of the decade/hex/octal freq divider...

errr, oh wait, you are speaking of the ancient stuff from museums!
That is simple, the crystal (if present) and/or coil and cap...

hey, you didn't sneak a freq doubler in behind that osc, did ya?

geesh... any cber would know that, well, after he read it...

and you ain't sneaky and tryin' to run off a harmonic of that osc, are ya?

ROFLOL!!!!

Yes, remember ignorance is bliss. Follow Dave's advice; even better
though, never ask a question here at all. That way, you can spend more
time on the air and that is more important than possibly learning
something about antennas and transmission lines.

The term "space wave propagation" does not necessarily mean that the wave has to be reflected from the ionosphere (or anything else) to be useful. Microwave systems, FM and TV broadcasting, aeronautical communications, satellites, and many other point-to-point systems at VHF and above all use a space wave. Reflection/refraction of it whether from the ground, structures, or (occasionally) the ionosphere are not always beneficial to those systems.

C'mon Cecil, you've been licensed long enough, at least as long as I have, to know that a 'swinging choke' changes the center of percussion on a baseball bat. It allows for a quicker swing. :-)

Now, if your antenna has a large capacitive component as part of it's input ... then quite possibly a swinging choke might help.

But, if your HV power supply needs to limit inrush currents then ...

Back to my comment. I was interrupted as my XYL was leaving for work.

Seriously, for the younger ham reader. The older AM transmitters, vacuum tube type, required continuous plate current at rated power. It was necessary to keep full plate current even in the absence of audio. A swinging choke, one with an critical inductance value that changed as a function of 'DC' current [variable reluctance] , as the first component of a HV supply, simplified the requirements on the other components of the HV filter circuit. Namely, the first input capacitor. High power HV supplies were typically designed using a double 'L' filter, choke input. The first choke provided better performance if it had a variable reactance as a function of rectified current. The minimum value of reactance [critical inductance] was a feature of the 'swinging choke'.

Ah!! The good old days. Radios were radios that worked all tv sets, stereos systems, and am broadcast receivers. I ran a 6AG7/6L6 at 10 watts on 15 meters CW and worked ALL tv sets [ALL] within 1/2 mile. I used a good quality DRAKE LP filter, a Pi network tuner, and had very low harmonic output and still worked all TV sets.

Question to the younger crowd ... Why did I have TVI?

Cecil, you should not answer. But, I suspect you had the same experience. Note: Cecil and I both have formal technical training.

Back around 1954, I put 600 feet of copperweld in the air,
fed by a modified ART-13 running 500 watts. The lights
in my room would dim during key down.

The closest TV transmitter was 90 miles away in Houston.
Madisonville, TX had no TV cable system at the time. When
I fired up, I wiped out TV reception for a good 100 square
miles. My parents took the ART-13 away from me, made me take
down the 600 ft. random wire, and go back to my 40w Globe
Scout and 40m dipole. :-(

I also came through rather distorted on a local church's
sound system. Some of the congregation thought that God
was speaking to them in an unknown tongue. :-)

I like the 75 ohm because it is a good match to the dipole. If you do the 300 ohm line and make the driven element a folded dipole out of the same twin lead, it will also be a good match.

Usually I have found it works well even without a good match on a dipole because the twin lead is generally a low loss line and the radiation from the feed line does not really reduce the usability of the antenna.

A poor match will be inclined to generate TVI and sometime get RF back into the shack. Also, some of the newer radios will not drive anything other than 50 ohms.

Most likely you have a tuner or you would not be considering a balanced line anyway.

If you go with the 75 ohm scheme and feed it directly from a "modern" transceiver it will probably still work pretty well but it will be likely to generate TVI.

If luck is on your side, the 300 ohm feed MIGHT work too, but not as you intended.

Whatever you choose, start at low power & work your way up.

I cannot figure out what you said that generated so many juvenile responses. It sounds like a reasonable question to me.

Ever noticed that luck favors the knowledgeable?

Multiples of 1/2WL length will work for any characteristic
impedance. The 300 ohm twinlead is less lossy than 72 ohm
twinlead. If 64 ft. is a convenient length for his feedline,
300 ohm twinlead is a good choice for a 1/2WL dipole probably
not requiring a tuner. An added advantage is that it may also
work well with a tuner on some of the higher frequencies.

Could somebody please explain why feedline SWR should produce any more general TVI in the neighborhood than if the match is perfect?

If the match is perfect, the antenna radiates all the power from the tx (less line loss). If anything else radiates part of that tx power (the feedline, you say), the total radiated power still can be no more than when the antenna radiates all of it. So if tx harmonic levels are the same in both cases, why should "feedline radiation" have much affect on TV receivers in the neighborhood?

Are you talking about some very localized effects (tx feedline running next to your own TV set or TV antenna, etc)?

<snip>

Would that explain why my tuner can only get a 2.6:1 match on 12m
with a 50 foot section of ladder line? Here's my (probably wrong) math:

((246/24.940)(0.92)5)= 45'4.5"

That's 246 / Freq x Velocity Factor x 5 (odd quarter wavelength)

On a related issue, my lowest SWR went from a broad 1.6:1 to a
narrow 1.1:1 after it stopped raining. Was that the wet asphault shingles
effecting the ladder line or just the wet ladder line? If it's the shingles,
I could elevate the line but either way, my tuner handles it. Should I care?

I've now plotted the SWR and (dry), the curve is nearly the same
as it was before I raised the antenna - it's just centered about 45 khz
higher and a bit narrower. This is with the tuner in bypass mode.

Thanks for all the help, guys!

Ken

Calculated values rarely ever take all the variables into account.
Virtually all calculated values have to be adjusted, i.e. cut
and tried, to achieve the desired results. What SWR do you get
when you increase the length by one foot? What SWR do you get
when you decrease the length by one foot?

> On a related issue, my lowest SWR went from a broad 1.6:1 to a

Do you care? :-) It is a good idea to keep ladder-line a few
inches away from anything that might adversely affect it. That
includes wet asphalt shingles.

Today's newer breed of hams will never have such marvelous experiences.

Funny thing though, even though I earned the WATV interference award on
my first weekend it took almost two weeks to work my 'Elmer' across town!!

It sounds like you've confused feedline SWR with feedline radiation. Those are two different effects. A line can have 1:1 SWR and radiate, or 10:1 and not radiate. SWR is determined solely by the differential load impedance and the line Z0. Feedline radiation is determined only by the amount and distribution of common mode current on the transmission line and of course its length.

The line SWR can be altered only by impedance matching at the load or changing the line's Z0. Feedline radiation is reduced by using one or more current baluns (common mode chokes) or a tuner with an inherently balanced output such as link coupling. While changing the feedline radiation can change the SWR (by changing the radiating part of the antenna), changing the SWR by altering the differential load impedance has no effect on the common mode current and hence the line radiation. (Anything which alters the common mode impedance of the antenna, which depending on its design a differential matching circuit might do, can change the line radiation. But it's not because of the change in SWR; it's because of how the matching circuit alters the common mode impedance.)

Only feedline radiation is associated with TVI; SWR isn't.

Feedline radiation can cause increased TVI and other RFI if the transmission line is routed in a way that it can couple to power lines,

telephone lines, TV cable, and other conductors which take RF into homes and close to TV sets and other electronic devices. (I've had more trouble with modern telephones than anything else.) Radiating antennas can, of course, do the same thing and to an even greater degree -- an attic transmitting antenna can often cause problems, for example. But feedline radiation can increase the RFI potential of an antenna that's otherwise far away from other conductors. The problem is simply one of effectively bringing part of the antenna into the house. It is, as you say, a localized effect, although it can affect a neighborhood by conduction and radiation from the conductors into which the feedline radiation is coupling.

Roy:

Even if you have me bit-bucketed, thanks for that info.

I am one who was ignorant to what you present in your text--I always expected increased line radiation with a mismatch. Now that you have stated it in text, it is plain a balun would prevent most if not all of this...

I will re-evaluate and brush up on what I have certainly missed before.

Warmest regards,
John

3531. Vertical (Butternut, Titan) vs Carolina Windom

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-27 19:00:25 UTC
From: Joe Guthart <jguthart@comcast.net>
Message-ID: <iuGdneiScZRXRHrfRVn-3A@comcast.com>
Source record: 72597

I'm starting to explore getting a new antenna for HF ... thus far the options that I've looked at are a vertical ground mount with a counterpoise kit (can't really do radials in my yard). The models that have come up often are the Butternut HF9V and the Gap Titan. Both seem similar. The Butternut's are more expensive and the Gap Titan seems to have good reviews and then has a few folks who say it's worthless. Alternatively, I've looked at a horizontal such as a Carolina Windom. The problem I have with this is that I only have one large tree to tie off to. To do a horizontal right, I would have to have to use a mast for the other end. I've also heard and seen several people that have used some of the break apart masts to do this and they have ended up with a broken mast.

Any advice is greatly appreciated. Thanks.

John, the digital age can come to an end in a heartbeat. An EMP pulse may well wipe out the computers.

CW which requires nothing but the human mind to get data through will be with us to the end of humanity.

As hams we need to be able to provide communications under the worst imaginable scenario. I, and many of the hams on here could in short order build a simple transmitter and receiver capable of CW operation and get a message through. What if no one on the other end is capable of receiving the message?

I guess you can ride like Paul Revere as your car will no longer run unless you drive an old pre-computer model. The DMV may indeed be asking questions as to what to do when your horse takes a dump in public.

I don't care if the FCC and the rest of the world makes stupid decisions, I have no problems with anyone who enters amateur radio via slow/no code. My objection is with sacrificing a skill that may be required to save lives and property for the sake of increasing numbers.

Too bad a neat skill set was viewed as a determent...

A buddy of mine and I had some buzzers that were used as signaling devices on the city busses. We discovered that when we activated them they played hell with an AM radio. We decided that if we hooked a bunch of wire to each terminal of the buzzer contacts we might be able to send messages between our houses. He lived four doors down. Armed with the buzzers and a couple of Philco radios we were in business.

Seems we had rediscovered spark gap transmitters much to the consternation of the neighbors. All went well until our neighbor six doors down, John Cummings W8DSL, took umbrage to our mode of transmission. Seems he could read code even better then we could and soon ferreted us out.

For a couple of ten year olds it was a lot of fun messing up Stella Dallas et al that our moms listened to.

>Could somebody please explain why feedline SWR should produce any more
>general TVI in the neighborhood than if the match is perfect?

My guess is that this belief is true in some cases... specifically the
following:

- You have a dipole, or other balanced antenna
- You're feeding it with coax
- The dipole has a feedpoint impedance which is high (resistive
and/or reactive) at the frequency of interest
- You don't have a balun at the feedpoint, or your balun has only a
modest amount of choking reactance
- Your coax is somewhere near a half-wavelength long (or a multiple
thereof) from the antenna to the point at which its first ground
occurs.

In this situation, you're likely to have a lot of RF on the outside of
the coax, as its braid will present a path for the ground-side current
which is significantly less than that of the antenna. You could end
up with "RF in the shack" problems, or the various other problems
which can result from having high levels of RF flowing near other
consumer-electronics devices.

If your feedline happens to be parallel to a cable-TV line, its
radiation may tend to induce a significant RF current on the outside
of the cable-TV coax, and might bleed to the inside. This could
result in fundamental-overload problems in the TV or distribution
amplifier.

If your feedline runs near a metal gutter or downspout, or near a
stucco wall with chicken-wire mesh in it, it might induce strong
enough RF currents to cause rectification noise in the joints, and the
generation of undesired harmonics of your transmit frequency which
might fall into the TV frequency band. Similar generation of
harmonics can occur, I gather, if you push a ferrite-core balun too
hard, and saturate the ferrite.

If I recall correctly, 6-meter operation is notorious for causing RFI
due to both fundamental overload (Channel 2 is often affected due to
its proximity to the 6-meter band) and to second-harmonic spurs
falling in the FM band.

If you've got RF coming back down into the shack, you might have some
of the RF-ground current getting into your household AC power ground,
and bleeding into the TV sets via their line cords.

All of these are things which can occur with any antenna, of course... they're just exaggerated (to whatever extent) by RF-on-the-coax due to the RF's greater proximity to the affected TVs.

In all of these cases, I'd expect problems to be more apparent for nearby TV sets (same building) than those far away. In urban areas, with people living in apartments or condos, the "neighborhood" can consist of quite a few people living in individual households within 100 feet of the transmitter and antenna.

actually, it takes a bit of wave shaping to get that square, saw tooth or ramp
into a decent sinewave out of most of the digital signal sources osc's...

you don't need to start with a perfect sine being produced at the osc level...

John, this business about problems caused by radiation from feedlines is very much exaggerated. It occurs far less frequently than it is mentioned on this newsgroups. It's just something to waffle about.

It's perfectly obvious far more near-field interference occurs due to radiation from the ANTENNA. Especially when the beam is pointing towards the house.

The antenna is designed and intended to radiate. Whereas the feedline only does it because of occasional imperfections and by accident. Most of the time it is not detectable as interference from either antenna or the line.

{Actually, it is nonsense to discuss things in terms of separate radiation from line and antenna. I am obliged to do so here to make myself understood and avoid accusations of trolling.}

Reg:

I think I got you on this point, my observations have indicated that some times the antenna is REALLY the antenna, however there are other times when the "antenna" can consist of BOTH the feedline and the antenna...

Long time ago I did some experiments with a fsm which could only "see" the coax and not the antenna--I introduced mismatches at the point between antenna and coax--perhaps by accident there was a correlation noted?, each time a mismatch was seen to introduce increased line radiation on the fsm, I just thought this would always be the case, now I am placed back in doubt...

... thanks reg, but don't let them give you that "TROLL LICENSE" though, you don't deserve it!

Besides, there is element 1 which has to passed first, the ability to send "TROLL MORSE" at "twenty-troll-words-a-minute." You'd never succeed reg :(

John, no one has ever been "forced" to learn CW to become a ham. Everything in life has a price of admission. You may choose to pay the price or not.

I have never heard of "press gangs" capturing people and forcing them to learn CW.

Neither have I seen a movie titled "Two Years Before The Key"

Like I say, I don't have a dog in the code/nocode fight. I personally feel that it is a necessary tool. YMMV

Fred:

There is no "price of admission" which needs be paid, the tests should reflect a logical, necessary "instruction" for what a guy/gal will need to get a radio and enter the hobby on level which is inline with his/her interests...

Morse has no place in this age, few will ever be interested in a key... if they are, no one will stop them from picking one up.

Long live amateur radio, and long stay dead the key...

John

Ken, this is all a bit scant on detail, and can't be interpreted with
certainty, so i am probably wasting my time running the numbers.

All the following in premised on my interpretation of your rather
loose description, and is only applicable to your situation if what
you have done is *very* close to my interpretation.

I think you have said you have cut a 135' dipole down to 7Mhz, so if
that means it is a half wave long at 7MHz, the feedpoint impedance at

resonance mounted low as you have described is probably somewhere about 60+j0 ohms.

If you transform that with 50' of ladder line (I have modelled Wireman 554), the Zin to the ladder is around 110-j310 and the ladder line has about 0.25dB of loss. You describe a coil of RG58 that seems to be 15' in length and a further 20' of the same. That will transform 110-j310 ohms to 5+j14 at the ATU end with about 2.5dB of loss. The RG58 operates at high VSWR (~12), and although relatively short, the loss is IMHO unacceptable.

There will be a little tuner loss, but it will be insignificant relative to the 2.7dB of feedline loss.

If you want to improve the configuration, the RG58 has to be a prime target of your attention. Most of the real power you deliver to the feedpoint will be radiated (ie conductor losses in the dipole are relatively insignificant), the challenge is to get the power to the feedpoint. In your case you are probably getting around 50% of the transmitter power to the feedpoint.

The closer the dipole is to ground, the more radiation is concentrated upwards, so if you want low angle radiation, raising the dipole height helps.

Owen

I should have added that the VSWR at the ATU end is as low as around
12, and is closer to 20 at the far end. (Knowing VSWR doesn't provide
the solution to this problem.)

John, I don't know if you do serious DX. But, I will witness that DX on CW is a heck of a lot easier and faster than on SSB.

As long as there is 'exotic DX' CW will live.

I posted this in the wrong group--Let's try it here.
==========
Hi again all,

It looks like I'm going to get a Butternut HF9VX vertical to replace my 25 year old Hustler 5BTV. I looked at Gap verticals, but in all the pictures I've seen, they seem to have some kind of horizontal array at the bottom. I plan on ground mounting this thing, and I'm afraid someone will trip on the array and destroy it or themself. My old Hustler had no horizontal elements at ground level, and in all the pics I've seen of the Butternut verticals, it looks like there is nothing sticking out at the bottom either. Is there anything at the bottom of the Butternuts, and what's your experience with them ???

Two points of advice:

1. Don't post in HTML!

2. Take a look at the Cushcraft R8 and the Hy-Gain AV-640 (which is similar, but has no traps). You also might want to study the K7LXC/N0AX report on verticals at . This report
compares measurements of several popular verticals.

"Irish expatriots" ?
That'd be another euphemism for "financers of terrorism" as Dubbya
refers to those backing Bin Laden & Co. Huh?
Do I detect the first nauseating whiff of history being rewritten, to
expunge all traces of Stateside involvement with funding Irish
terrorism?

It's just a shame that Martin McGuinness is (according to US news
networks) in the US telling American financial backers, before
announcing to everybody else, that the "armed struggle" aka
terrorism, is being called off.
This is how it works. First you tell your bank, then you tell the
rest. That way it keeps your bank sweet for the next time you want
more bucks.

Big Mac.

3558. ARRL 20 july, FCC Proposes to Drop Morse Code Requirement for All License Classes

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-28 07:37:24 UTC
From: Thierry <->
Message-ID: <42e88b37$1@news.vo.lu>

FYI - FCC Proposes to Drop Morse Code Requirement for All License Classes

Thierry, ON4SKY
http://www.astrosurf.org/lombry

Text found on ARRL at http://www.arrl.org/news/stories/2005/07/20/100/?nc=1

NEWINGTON, CT, July 20, 2005--The FCC has proposed dropping the 5 WPM Morse code element as a requirement to obtain an Amateur Radio license of any class. The Commission recommended the change to its Part 97 Amateur Service rules in a Notice of Proposed Rule Making (NPRM) in WT Docket 05-235. Any rule changes proposed in the NPRM would not become final until the FCC gathers additional public comments, formally adopts any changes to its rules and concludes the proceeding by issuing a Report and Order (R&O) spelling out the changes and specifying an effective date. That's not likely to happen for several months. The FCC declined in its NPRM to go forward with any other suggested changes to Amateur Service licensing rules or operating privileges beyond elimination of the Morse requirement.
"Based upon the petitions and comments, we propose to amend our amateur service rules to eliminate the requirement that individuals pass a telegraphy examination in order to qualify for any amateur radio operator license," the FCC said in its NPRM, released July 19. This week's NPRM consolidated 18 petitions for rule making from the amateur community--including one from the ARRL--that proposed a wide range of additional changes to the amateur rules. The FCC said the various petitions had attracted 6200 comments from the amateur community, which soon will have the opportunity to comment again--this time on the FCC's proposals in response to those petitions.

The Commission said it believes dropping Element 1--the 5 WPM Morse examination--would "encourage individuals who are interested in communications technology, or who are able to contribute to the advancement of the radio art, to become amateur radio operators." The FCC said it also would eliminate a requirement it believes "is now unnecessary and that may discourage" current licensees from advancing their skills, and that it would "promote more efficient use" of current Amateur Radio spectrum.

The FCC cited changes in Article 25 of the international Radio Regulations adopted at World Radiocommunication Conference 2003 as the primary reason to go forward with eliminating Morse code as an Amateur Radio licensing requirement in the future. Among other changes, WRC-03 deleted the Morse testing requirement for amateur applicants seeking HF privileges, leaving it up to individual countries to determine whether or not they want to mandate

Morse testing. Several countries already have dropped their Morse requirements.

ARRL CEO David Sumner, K1ZZ, said he was not surprised that the FCC proposed altogether scrapping the Morse code requirement. The League and others had called for retaining the 5 WPM requirement only for Amateur Extra class applicants. Sumner expressed dismay, however, that the FCC turned away proposals from the League and other petitioners to create a new entry-level Amateur Radio license class.

"We're disappointed that the Commission prefers to deny an opportunity to give Amateur Radio the restructuring it needs for the 21st century," he said. "It appears that the Commission is taking the easy road, but the easy road is seldom the right road."

Sumner said ARRL officials and the Board of Directors would closely study the 30-page NPRM and plan to comment further after they've had the opportunity to consider the Commission's stated rationales for its proposals.

In 2004, the ARRL filed a Petition for Rule Making asking the FCC to amend Part 97 to complete the Amateur Service restructuring begun in 1999 but "left unfinished." The League called on the FCC to create a new entry-level license, reduce the number of actual license classes to three and drop the Morse code testing requirement for all classes except for Amateur Extra. Among other recommendations, the League asked the FCC to automatically upgrade Technician licensees to General and Advanced licensees to Amateur Extra. In this week's NPRM, the FCC said it was not persuaded such automatic upgrades were in the public interest.

The FCC said it did not believe a new entry-level license class was warranted because current Novice and Tech Plus licensees already can easily upgrade to General. "We also note that, if our proposal to eliminate telegraphy testing in the amateur service is adopted," the FCC continued, "a person who is not a licensee will be able to qualify for a General Class operator license by passing two written examinations, and that a person who is a Technician Class licensee will be able to qualify for a General Class operator license by passing one written examination." The FCC said it does not believe either path to be unreasonable.

The FCC also said that it's already addressed some of the other issues petitioners raised in its "Phone Band Expansion" (or "Omnibus") NPRM in WT Docket 04-140. In that proceeding, the Commission proposed to go along with the ARRL's Novice refarming proposal aimed at reallocating the current Novice/Tech Plus subbands to provide additional phone spectrum. Under the plan, Novice/Tech Plus licensees would be granted CW privileges in the current General CW subbands.

A 60-day period for members of the public to comment on the FCC's NPRM in WT 05-235 will begin once the NPRM appears in the Federal Register. Reply comments will be due within 75 days of the NPRM's publication in the Federal Register.

3559. Re: Vertical (Butternut, Titan) vs Carolina Windom

"Joe Guthart" <jguthart@comcast.net> wrote in message
news:iuGdneiScZRXRHrfRVn-3A@comcast.com...
I'm starting to explore getting a new antenna for HF ... thus far the
options that I've looked at are a vertical ground mount with a counterpoise
kit (can't really do radials in my yard). The models that have come up
often are the Butternut HF9V and the Gap Titan. Both seem similar. The
Butternut's are more expensive and the Gap Titan seems to have good reviews
and then has a few folks who say it's worthless. Alternatively, I've looked
at a horizontal such as a Carolina Windom. The problem I have with this is
that I only have one large tree to tie off to. To do a horizontal right, I
would have to have to use a mast for the other end. I've also heard and
seen several people that have used some of the break apart masts to do this
and they have ended up with a broken mast.

Any advice is greatly appreciated. Thanks.

Hi Joe,

I worked with a Hi-Gain vertical placed 10m high for Dxing and a G5RV and
carolina windom (30-40m long) at 100W SSB.
Based on my exprience, as it, the advantage goes definetly to the vertical
due to its omnidirectional pattern (even placed at ground level with
radials).

Dipoles display a leaf radiation pattern which is a plus vs. the vertical
but there are set in specific directions and elevations which is not always
interesting if you want to reach a specific DX zone.
In my case for example the windom was tied NE-SW in ON so I had difficulties
to work USA over the eastern coast, even canada, middle east, africa and
farer.
Of course, from time to time I reached XE, PY, YB at eve and even VK on
mornings but it was sometimes hard
(mainly due to kW-users !!).
The vertical segment of the OCF is a plus vs. e.g. a G5RV as it emits at
360°, adding some lobes in troughs of the OCF radiation pattern. Thus
gobally, I have found the OCF offering almost an omnidirectional pattern
http://www.astrosurf.org/lombry/Radio/ant-carolina-windom-radiation-pattern.
gif
and working better than my multiband dipole but not as good as the 1/4L
vertical.
Now if you can rotate your dipole or OCF, I would use it instead of the
vertical.

Lets work our way backwards. The Butternuts work well. Since you are
used to vertical performance, you should be happy with one of them.

As to things sticking out at ground level, the Butternut wants some
radials around it. You'll want to place some on or in the ground. Some
staple the radials to the ground surface. A lot of us bury them a bit
underground. So there are no trip hazards.

3561. Buzzz on my Wellbrook ALA 1530 loop

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-28 14:49:33 UTC
From: Mark Veldhuis <me@privacy.net>
Message-ID: <dcar9t$259$1@news5.zwoll1.ov.home.nl>
Source record: 72527

Hello,

I got my Icom IC-R75 rx. connected to a Wellbrook ALA1530 loop antenna.
On this antenna, I have an enormous amount of 'buzzz' on much MW and SW
frequencies. It is much less noticeable on a portable receiver with a
whip antenna.
When I have just the center pin of the PL259 plug connected to the
receiver, much of the buzz disappears. As soon as I connect the other
part of the plug too (the shield of the coax, so to say), it becomes
audible again.
I am not very techinal, and don't know where to start troubleshooting.
Should I look for damage on the coax cable? Could it be badly
soldered/connected BNC plugs? Anything else that's worth investigating?

Many thanks for any tips!
--

73',

Mark Veldhuis.

Hi Mark,

Sounds like a ground loop. If you are using the Antenna Interface,
make all connections that give you this interference. Now, disconnect
the power lead to the Antenna Interface. If the noise goes away, you
have a ground loop that is associated with where your power to this
unit comes from, and what you are using as the ground for your
IC-R75.

>a swinging choke ??

I believe that a goodly percentage of fixed-frequency quartz crystal
oscillators use a Colpitts configuration in their feedback circuitry.
Pierce topologies are likely used, as well.

The L in such oscillators is the motional inductance of the crystal,
rather than the inductance of a wire-wound inductor, but the principle
is still the same.

>Then why ask these questions on a 2005 Ham test ??

Because the circuits are still relevant, to either modern ham gear, or
to the older gear that many hams refurbish and use, or to both.

>Maybe ask about a VCO or a crowbar circuit ??

VCOs require some form of positive feedback in order to oscillate.
This can be in a Colpitts configuration just as well as in any other.

Questions about a crowbar would certainly be relevant as well.

The Ameritron ALS-600 solid state amplifier uses a swinging choke in its 50 volt 20 amp power supply. The choke is essentially the regulating element because it swings in and out of core saturation. I understand they now have a SMPS that they will offer with the ALS-600. Maybe they should have some questions about SMPS on the exam.

You miss the point! Totally missed the point!!

In the 'olden days', the exams were not multiple guess questions; and,
they were answered in front of an FCC Engineer. In the olden days one
had to commit to some real effort to get a license. In human nature we
VALUE that which we work for or invest for.

The crime in ham radio today is the 5 hour Saturday morning cram session
followed by a VE session; followed by a license; followed by loss of
interest in a year or so.

I live in a small town with 14 licensed 'hams' with only one active [me]
and only one HF station [mine].

IMO there is a significant difference between number of licenses issued
or valid and how many hams are on the air.

3573. Underground Antenna Experiments on 160 meters.

Some years back I buried a 30 metre (60-feet) auminium wire one spade depth in my back garden. Wire was 1.5 mm in diameter. Soil resistivity about 100 ohm-metres. To scientists that's 10 milli-Siemens. The near end of the wire came up in the shack. That's under my kitchen sink. It's still there. Open-circuit at the far end.

As a counterpoise, something essential to tune it against, I erected a wire in the form of an inverted-L. This was about 30 feet high and overall length about 140 feet. I chose this length because it fitted nicely into my back garden. The front garden is too short even for an underground antenna.

On the 160m band I fed into it about 30 watts from a home-brew transceiver so I can't provide for the record a manufacturer's type and serial number. However I still have the transceiver which can be inspected.

Despite a high local noise level of S-6 I was able to communicate up to 60 miles with mobile stations in broad daylight on SSB. After sunset I could easily communicate with most of Europe on CW.

I think a record of these buried antenna experiments should be kept for posterity, alongside the famous biblical work of B,L & E.

By the way, as you see, I did remember to measure soil resistivity. It was the first thing I did. What buried wire do you think I used to measure it?

All of them!!! The reference oscillator in every phase locked loop is
generally a Colpitt's oscillator. I suspect that every oscillator in
the VCO circuit is also Colpitt's.

By simply asking the question you make the point!!!

The required level of knowledge for a license today is significantly
poorer than 40 or 50 years ago.

White noise is a critical requirement of the Colpitts/Hartley oscillator
design.

Nothing new here!

You say you don't know why White noise is required. Better go read
Terman or other credible designers.

I use an old DRAKE. But QST rated the YA-1 as among the best. I have
no, none, zero, zippo, nil, interest in Bencher or this listing.

Hi Reg, Interesting, but isn't a 30 metre wire more like 100 feet
instead of 60 feet? According to the conversions on your programs it
is. Did you ever try burying your counterpoise and elevating the
buried aluminum wire to see how the results compare?

So you loaded your tx into an antenna system consisting of a 140 foot inverted L, 30 feet above ground with a buried ground radial 99 feet long. What is so unusual about that? Certainly not a venture of biblical proportions, IMO.

Perhaps you haven't flipped enough of your calendar pages?

It's in the right ball park.

I'm pleased you make use of the measurements conversions in some of my programs. Its just a small thing I can do to help paying back for what you Americans did by helping us poor Brits to win the war. ;o) ;o) ;o) ;o) ;o) ;o)

Reg:

Indeed, my grandfather fought with "you brits" during the war, he had many german lugars, swords, coins and memorabilia he brought back...

He seen enough to hold a high respect for the british empires' citizens--for the rest of his life... indeed, his words inspired such in others...

Unless he greatly exaggerated the acts of glory, valor, bravery and loyalty demonstrated by the british troops, (which I never found existed in my grandfather--exaggeration), which he shared foxholes with, you brits have nothing to repay... we are even--perhaps we even got the better of the deal, as our forefathers had the company of decent men to share those bad times with... he was there and liberated the Nazi camps, in the end... he would cry when he would describe what his eyes could never forget...

... he spoke highly of the aussies also, indeed, he commented, "some of those men were above mere human beings" (his EXACT words), when referring to both brits and aussies.

I have told my son of this man (his great-grandfather) and the men he (my grandfather) was fortunate enough to have had at his side...

If the future demands, let us hope we shall be such allies again...

Hmmm...

No, I don't believe I will have to read anything...

But, if you can't tell the difference between a white noise generator and an
osc giving a clean fundamental signal with greatly suppressed/filtered
harmonics (or even, non-existent harmonics), you may wish to read-up before
taking that project to the air...

You can't go wrong with either antenna. Do know that the Titan comes in
two versions one for 80 and one for 75. Do not use your tuner with the
Titan, It's all in the directions You will love either one of 'em.

... not at all...

... some are cmos/mosfet nand/nor gates, xtal controlled feedback--used as osc's and only tuned by "pulling" the xtal with a cap, and the signal passed to multipliers (multishot monostable vibrators) or freq dividers (dec/hex/oct) and used with other signals (mixed) to produce still other/unique freqs.

Special purpose ic's are around which contain all this (except the xtal) on a single chip.

There is probably much newer technology than this at this point, as all my knowledge of this hardware is a decade or more old...

The cheapest/easiest equip uses a coil and cap (old vfo's) and/or xtal (vxo's.)

The same day I took the test for General, I also took and passed all requirements for a first class Phone with RADAR endorsement. The engineer administering the test told me if I wanted to take a really tough test, the amateur extra was the most difficult given by the FCC.

Unfortunately at that time one had to wait a year to take advanced and two years to take the Extra. I would sure like to see them reinstate the time requirements so some of these young bucks could get a little seasoning before advancing. Today you can get it all in one day. Then armed with your brand new Extra; proceed to E-Ham and ask questions in the Elmer conference that could be answered by an old time novice.

Fred:

Yes. But those were simple times when much of what we take for granted today loomed before us as dark mysteries...

Things are much more complex these days, BS, MS, PHD's are much more common per capita and the general knowledge of the common person on the street is magnitudes greater than the times you are speaking of.

No longer are people with a bit of knowledge in such demand.

Our colleges turn out highly educated individuals in vast numbers which stagger the imagination. Indeed, seats in colleges are filled far too quickly, leaving no room for those not fortunate to gain entrance.

It is quite possible the person you see before you in a lowly public service position has a degree.

Across the board, +25% of all college grads are working at or near minimum wage in a field outside their course of study--five years after they graduate; I suspect this figure, which the colleges themselves claim, is rather low...

John, I'm very serious when I say that 'white noise' is critical to Colpitts/Hartley oscillator operation.

The feedback equation for oscillation requires a voltagecurrent gain greater than 1 and a phase shift of 180 degrees [in simplified terms].

Starting conditions, in the absence of white noise, has zero input voltage and hence zero output voltage and therefore no oscillation! The presence of white noise provides the starting conditions, the Vin to be amplified, and the tuned circuit, L and C, provides the frequency discrimination, and the fundamental frequency of the oscillator. The Capacitive voltage divider [Colpitts] or the Inductive voltage divider [Hartley] provides the feedback factor. The active device, tube, transistor, FET, etc. provides the gain and contributes to the phase shift.

White noise, frequency selectivity, gain greater than 1, and 180 degrees phase shift are absolute requirements for an oscillator. In the absence of any one there is NO oscillator. The white noise provides the starting conditions for oscillation!!!

Does that mean you don't maintain your equipment or know what to look
for when you open the cover?

Amateur Radio is supposed to encourage self learning in some [SOME]
phase of the electronic disciplines associated with the generation,
transmission, and reception of electromagnetic signals.

I consider that self learning requires more than finding and using the
ON/OFF button.

Ham op:

Absolutely! Any amp is an oscillator, any oscillator is an amp... just depends on how ya use it (mainly feedback.)

There is also the subjects of "thermal noise" and "quantum noise", both contribute to the ease which with a circuit begins and sustains oscillations...

Well, unless the laws of physics have changed!

John

Ham op:

Just where do you get a soldering iron which is small enough to deal with smc components, these boards are done by machine. The world has gone surface mount technology yanno...

I only work on the mikes, low pass/high pass/bandpass filters, linears and feedlines, antennas, parts which are still big enough to handle...

My receiver is a PCI card for my computer (100khz-180Mhz, there are a couple of birdies on the 2.8Ghz it is mounted in, these were not apparent when it was in a 900Mhz motherboard) and the xmitter is a continuous full coverage 3-5 watt transmitter PCI card 100khz-250mhz... computer sound card doubles as the output audio for the receiver and dsp mike input for the transmitter... driver/linear is external... different faces(skins) for the receiver (on the monitor) are software selectable, any mode is possible, with the proper software--even those NOT invented yet...

My "equip" is pretty much my computer these days, but I do have some ancient gonset, johnson, hallicrafters, drake which I have not used in over a year.

Got some heavy duty chicken band equip too, but the computer is highly capable of 11 meters, but not type accepted for CB...

John

Nonsense John, today's college graduate is more in line with the high school graduates of the fifties. I hired enough of your "highly educated" graduates to be more than a casual observer.

They knew every thing there was to know about political correctness, liberal thinking, and how to bitch if they were not given everything on a platter the day they hired in.

I assigned an engineer the task of designing a simple serial interface to a piece of equipment. He told me "we didn't cover that in school". Today A's are passed out to everyone, in some schools, so as not to make the others feel bad.

Give me an old time ham or a Navy trained technician, at least they had the basics. Many of today's graduates are over paid at minimum wage.

Like I said before... You seem all too willing to conform to the
standards and practices of the HAM world. What is so different about
this forum, and doing things the way they have always been done here?
Why do you have to blatantly display your unwillingness to conform to
what has long been the accepted practice?

Screw you, and your hypocrisy.
Yet another idiot, you are.
The word for today is CONFORM

Fred:

I disagree. Most of the problems we see in academia is that the mindset has changed. Older personalities have quite some difficulty in coping with the new generations, it has always been like that though, just more intense in this age (but what isn't?)

The oldsters have a "control freak" attitude which the youngsters are not properly trained to deal with, I think the parents used to take care of this, and we in academia have failed the youngsters in not picking up as part of their training and education, when the mothers left home for work.

And these new grads are a real and present danger to the oldsters, and we know it. The corps know it to, they can have a handful of these new grads for what one of us old farts demand for our "experience." (ancient historical knowledge)

I felt them a threat to, and the young guys with those new minds can come up with new ideas with blazing speed. R&D ends up being a roomful of these guys and one old guy keeping heard over their "enthusiasm."

The "generation gap" is wider than ever, and you need the "right guys" in senior positions which can interact with the new minds. Truth is, if you are 55 these days, you'd better think about retiring--before you embarrass your self or others about you...

The world is changing as much as when the cotton gin was invented--most of the people back then died off without never being able to adapt to the "industrial age." We are just seeing it happen all again, but many are unaware of this history--and so end up repeating the same mistakes.

Hi,

In article <4avhe1duludfoedb8nu7g480man5miej6v@4ax.com>,
kb7qhc@comcast.net says...

> Sounds like a ground loop. If you are using the Antenna Interface,
> make all connections that give you this interference. Now, disconnect
> the power lead to the Antenna Interface. If the noise goes away, you
> have a ground loop that is associated with where your power to this
> unit comes from, and what you are using as the ground for your
> IC-R75.

I remember trying that before, and it did stop the noise indeed.
But... If it's a ground loop, wouldn't it be there all the time?
I'm asking because I came home tonight, connected the antenna, and...now
noise, no buzz! That too happened before, but the noise was back less
than half a day later. :(
So, could this still be a ground loop? And if so, how do I go about
getting rid of it? Is it an easy thing to do for someone non-technical
like me?

I am not using any ground for my R75 at the moment. With my previous
antenna setup, a longwire with MLB, I had a ground rod. And it did
absolutely nothing, it didn't make any difference at all...

Thanks for the help!
--

73',

Mark Veldhuis.

Okay, draw me a circuit of a Colpitts VCO. Why you apparently think
these are obsolete is beyond me. All sine wave oscillators, LC or
crystal, are basically the same circuit with the only variable being
the location of the rf common point.

A lot of modern high voltage supplies would be better off if they had
swinging chokes in them. My "modern" 8877 amp power supply uses a
resonant choke.

Wes:

Those osc are a thing of the past...

Bring a junk am broadcast radio near your computer, you will hear literal
dozens (well, a bunch anyway!) of osc's freqs going on there, probably not one
being generated by a colpitts, hartley or pierce osc circuit...
And, with the proper processing, all those waves could be a sine...

Thanks to everyone for the help/tips/theory on my 40m & up
antenna project. It's working fb now.

Note: the 1.6:1 minimum SWR I was seeing went away after
the sun dried off the roof and feedline. Now I get a 1.1:1 or
better match. Still can't get a decent match on 12m. On 10m
my autotuner (Elecraft KAT2 internal) has to work hard to get
a match. It's not my only antenna for the upper bands so I'm
not too concerned.

Don't be silly! The first thing any new ham learns on the internet
is that if you got your Extra after the 20wpm requirement was dropped,
your questions will meet with nothing but scorn and derision!

Ben:

Be patient, we are in the process of upgrading all the elmers to no-coders now.
Give us time, this is a major upgrade and results cannot be expected
immediately.

John

Hi Mark,

Your experience indicates otherwise. This is not unusual. I've had
ground loops that depended on the weather. As it is frequently rainy
here (Seattle), my problems would come and go with the CHANGE in the
weather.

>how do I go about
>getting rid of it? Is it an easy thing to do for someone non-technical
>like me?

Move the Interface power supply to the same outlet that you use to
power your R75. Check the ground of the AC socket and make sure your
wiring is not reversed (usually done with a small tester sold in most
hardware stores).

>I am not using any ground for my R75 at the moment.

Unless you are running solely off batteries, have no other connections
to the R75 whatever, naturally you are connected to ground. You
simply don't know how it is getting to the R75 is all, and this is the
usual configuration of those who suffer from ground loops.

>With my previous
>antenna setup, a longwire with MLB, I had a ground rod. And it did
>absolutely nothing, it didn't make any difference at all...

That's unusual to say the least. But it points out that whatever
ground you thought you had in the "ground rod" was simply duplicating
what already existed through the AC distribution system.

Another way to confirm is to replace the Interface power supply with a
battery pack.

>You're looking at MAYBE a three percent improvement in signal. As the
>others have said, it's not broken, so why fix it?

If I understood Ken's configuration on 7MHz, on my modelling adding about 14' to the ladder line would reduce the losses in the RG58 by about 1.5dB, which is a 40% increase in EIRP. Of course, that addresses performance on 40m only.

That is a lot more than the unsubstantiated "MAYBE a few percent".

It is up to Ken if he wants to chase 40%... perhaps that is why he asked the question in the first place. He might have an interest in understanding and learning, he might be one of the remaining folk who think that ham radio is "for the purpose of self-training, intercommunication and technical investigations" (from ITU RR 1.56).

One might think from Ken's first posting that he wants this antenna for 40m solely, but then he expressed disappointment with being unable to match up on 24MHz, so that creates some suspicion that he may be looking for a multi band or all band antenna.

Ken, if you can't match up on high bands, it is a warning that the impedance is outside the tuner's capacity, and probably outside good performance. Similarly, if the tuner does deliver low SWR but is very sharp in tuning, it is an indication that the "loaded Q" of the tuner is high and probably excessively lossy. Beware of matching an unknown antenna and being satisfied that it is good so long as you can "get the SWR down".

I hired many newly degreed engineers in the 1980s. It took 5 to 8 years
of actual work before they became real engineers. Several engineers from
'highly' accredited universities were dismissed because they wouldn't or
couldn't write a simple technical report.

Check the Harvard University graduation list. EVERYBODY is a high honors
graduate!!! More than 90% of Harvard graduates are high honors. I find
that hard to believe.

Hi Reg,

My partner has built a similar antenna years ago with great success.

There are several antennas of this type in the world used primarily for military applications at the these bands.

If anyone is interested look at www.ve3sqb.com, maybe you can get him to post some of his research.

3620. Tuning the Butternut HF6V for 80 m

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-29 13:18:45 UTC
From: John N9JG <john@gotwals.xremovey.com>
Message-ID: <dcdabjaoi1@mailhub227.itcs.purdue.edu>
Source record: 72486

I am using a Palstar ZM-30 antenna bridge to tune my new Butternut HF6V vertical antenna. The antenna is ground-mounted, and the ground system consists of 32 wires with an average length of about 30 feet laid on the top of clay soil.

I have no problem finding resonance on 80 m, but the impedance at resonance seems to be low. The adjustment instructions for the HF6V state that air-wound coil (Q), at the base of the antenna, should be adjusted "for even lower VSWR" by stretching the coil. Coil (Q) is installed as a shunt at the feedpoint of the vertical.

I have made all measurements at the antenna, i.e., at the junction of the coax 75 ohm matching section and the main 52 ohm transmission line. When coil (Q) is fully compressed, length of about 2.5 in, I measure an impedance (at resonance) of 20 ohms (SWR?2.5) . When the coil is expanded to a length of about 4.75 in, I measure an impedance of 25 ohms, corresponding to an SWR of about 2.0.

The problem is that I have run out of lead length to expand the coil. Should I leave things where they are now, or should I wind a new coil with about half the turns and continue with my measurements?

In all likelyhood, the master clock oscillator for the microprocessor
is a Pierce xtal oscillator. All of the other garbage is derived from
that. There may also be plug-in cards with their own clock, most
likely another Pierce.

In case you've forgotten, these are -digital- circuits, sine waves
need not apply.

Why you guys think that the computer guys have invented some new
-magic- oscillator is beyond me. Wait a minute..... maybe I understand
after all.

==========
Harrold,

To be exact, 30 meters = 98.43 feet.

It was NOT a deliberate mistake to check on how much interest would be displayed in the experiment by readers. But it could have been. ;o)

I did swap the connections between antenna and counterpoise and, as you can guess, it didn't make a scrap of difference.

The underground antenna ended up in a bunch of other radials. But the best radial I have is the incoming domestic water main which is terminated at its other end by 100,000 miles of underground pipes feeding the whole of the Black Country (where it all began) and the Great City of Birmingham (which yesterday suffered a tornado due to Earth warming climatic changes caused by American pollution of the atmosphere).

It was only the day before that life in the city was disrupted by police raids on houses alleged to be occupied by unsuccessful suicide bombers. Birmingham, in opposition to Manchester, will do anything to get into the news!

Reg.

tclay@qmc.ph.msstate.edu wrote:
> You CANNOT superimpose POWERS, ...

Hi Tor, I appologize that the earlier energy flow chart
was not drawn as well as it might have been. I've expanded
that chart in the following and provided the power management
equations associated with the superposition of EM fields. The
'X' event is the initial reflection event at the first
discontinuity, point A. The 'Y' event is the initial reflection
event at the second discontinuity, point B. The 'Z' event is the
initial re-reflection event back at point A.

```
100W 1/4WL
XMTR---50 ohm---+--------100 ohm---------+---200 ohm---200 load
feedline A feedline B feedline
```

Just before the first reflection arrives back at A

```
Pfor(50) | |
100W-->--X |
X-->--+ |
11.11W--<--X \ Pfor(100) |
Pref(50) | +-->--88.89W-->--Y
| Y-->--79.01W
| +--<--9.876W--<--Y Pfor(200)
| / Pref(100) |
| <--+ |
| |
```

Just after the first reflection arrives back at A

```
Pfor(50) | Pfor(100) |
100W-->--X 109.67W |
X-->--+ |
11.11W--<--X \ P1 |
P3 | +-->--88.89W-->--Y
| Y-->--79.01W
Pref(50) | +--<--9.876W--<--Y Pfor(200)
0.139W | / Pref(100) |
Z--<--+ |
8.779W--<--Z |
P4 Z-->--1.097W |
| P2 |
```

P1 = Pfor(50)*(1-rho^2), P2 = Pref(100)*rho^2

P3 = Pref(100)*(1-rho^2), P4 = Pfor(50)*rho^2

How much destructive interference between wave(P3) and wave(P4)?

Pref(50) = P3 + P4 - 2*sqrt(P3*P4) = 11.11W + 8.779W - 19.75W = 0.139W

19.75W of destructive interference, negative since cos(180)=-1

How much constructive interference between wave(P1) and wave(P2)?

Pfor(100) = P1 + P2 + 2*sqrt(P1*P2) = 88.89W + 1.097W + 19.75W = 109.67W

19.75W of constructive interference, positive since cos(0)=+1

Destructive interference energy = constructive interference energy
(toward the source) (toward the load)

It follows that |P1*P2| = |P3*P4| in order to satisfy the conservation
of energy principle.

Nope the FCC makes the rules
You can beat up on the new non-technical hams OR help them
The choice is yours.
In our area, we run a weekly 2M Ham Help net
Our repeater is open to any technical question, no matter how basic.
Periodic classes are conducted for Tech and General -- success rate is quite high.

And many of our no-code Techs are very active in emergency communications, PR communicators, field day, and many other useful avenues of ham radio.
Quite a number have advanced to General and Extra.

The times is a changing -- Bob Dylan

Bob Dylan song lyrics

Come mothers and fathers
Throughout the land
And don't criticize
What you can't understand
Your sons and your daughters
Are beyond your command
Your old road is
Rapidly changin'.
Please get out of the new one
If you can't lend your hand
For the times they are a-changin'.

Ham op:

I am in my 50's, age is becoming a bit of a problem here, I can extrapolate and get some kind of a picture of it being a bit more of a problem for you then--if you are older.

Your posts certainly don't reflect such limitations, although we may be "out of sync" on some points, you pose good conversation.

Remember, when all is said and done, we must shake hands and have a drink together...

Wes:

By "master clock" (or bus clock), I take it the digital osc on my motherboard running at 266Mhz and exists as chip with an in-house part number only, can't really check.

I suspect it to be a UHF-high precision op amp with crystal controlled feedback used as an osc, or a set of digital logic gates with osc established though xtal feedback--either way, a square wave out.

But we had one thing lacking today, it is called respect.

You, just yesterday tried to point out to a poster his lack of respect for Roy. Accomplishments are viewed by the youth of today as a thing to distain, as it makes those who have accomplished nothing feel bad.

"Let's play soccer, but no score keeping so no one loses"

"It feels bad to lose, and we don't want to make anyone feel bad"

"Everyone should receive A's so no one can feel superior, making someone feel inferior is not a good thing"

"WE CAN'T PROFILE TERRORISTS AS IT WOULD CREATE NEGATIVE MESSAGES, MAKING THEM FEEL BAD"

Tor, N4OGW wrote:
"You CANNOT superimpose POWERS, or even talk about the "power" of
various reflections in the same media."

It is done all the time. P=Esquared / R = Isquared x R.

On page 99 of the 1955 edition of "Electronic and Radio Engineering"
Terman writes:

"The standing-wave ratio S is one means of expressing the magnitude of
the reflectiom coefficient; the exact relation between the two is:

S=1+absolute value of the reflection coefficient / 1-absolute value of
the reflection coefficient

or

absolute value of the reflection coefficient= S-1/S+1

Standing-wave ratio=S=Emax/Emin

This definition of standing-wave ratio is sometimes called voltage
standing-wave ratio (VSWR) to distinguish it from the standing-wave
ratio expressed as a power ratio, which is (Emax/Emin)squared."

Best regards, Richard Harrison, KB5WZI

Each of those oscillators use a crystal for frequency and stability!
Each of those oscillators uses positive feedback so that it oscillates.
Draw the equivalent circuit of those oscillators and you will find the
COLPITTS circuit !!!!

I wonder if you are confusing the Coplitts/Hartley topography with the
old VFO which were/are variable tuned [Colpitts/Hartley] oscillators.

Every digital frequency synthesizer uses a Colpitts oscillator as the
reference oscillator, at a fixed frequency, and the variable oscillator
is digitally phase locked to it.

The basic Physics and governing laws for oscillators has not changed.

I think he means that it does not occur in nature, and it therefore
shouldn't be done mathematically. That's because power doesn't
propagate, and
I hasten to add - neither do Poynting vectors. Nor does power reflect,
refract, or diffract. Power is a rate at which energy is transferred,
absorbed, or dissipated. It's not a wave which propagates. It's a
mathematical product of two of the characteristics of a wave that
propagates. Numbers on the other hand can indeed be multiplied, divided,
squared, added, and subtracted. We can often even get the right answer
when we do that with power numbers. But that fact can't necessarily be
extrapolated to mean that the given mathematical operation also takes
place in a transmission line. An that is what the author in question
is attempting to have us believe.

I've used an antenna made of buried radial wires for many years, with a vertical counterpoise, and AM broadcasters have been using this technique for the better part of a century. Works fine. Hm, maybe I should add another column to the wire specification table in EZNEC so people can specify whether the wire is an (A)ntenna or (C)ounterpoise. . .

A related antenna was described many years ago in one of the amateur magazines. The author explained that when we construct a vertical antenna, an image antenna appears in the ground. So he simply dug a hole in the ground in put his vertical below ground. The image antenna did the radiating, of course. I did a pretty thorough search of QST and couldn't find the article -- I'd be indebted to anyone who can recall where this appeared. My guess is that it was around the early '60s. In an April issue of course.

Now, that's an interesting concept.

The VSWR is the ratio of the maximum voltage anywhere along the line to the minimum voltage anywhere along the line (presuming the line is sufficiently long for a full maximum and minimum to occur). We can use a voltage probe to actually measure this voltage in a slotted line.

If the voltage is sinusoidal, so is the power, just at twice the frequency. (I'm sure you can find that in Terman somewhere, but it's simple to derive with a little trigonometry.) Since you say that power superposes, we should expect power waves to add and cancel just like voltage waves. And this should result in dips and peaks in the power as we move along the line, just like voltage, right? I'd expect the dips and peaks to be twice as closely spaced, however, because the wavelength of the power waves would be half the wavelength of the voltage waves.

So is the ratio of the maximum to minimum power along the line due to this superposition of power waves equal to the PSWR?

Hi Richard,

Given the original subject line has been munged up, it is difficult to know if you were responding to Tor directly, or through another posting. Either way, it would be instructive to complete his quote, as follows:

>>However, your understanding of superposition is wrong. You
>>CANNOT superimpose POWERS, or even talk about the "power" of various
>>reflections in the same media. You can only add the wave amplitudes
>>(electric fields). THEN you take the total amplitude and square that
>>to get the power.

which seems to "square" with where you take this:

>It is done all the time. P=Esquared / R = Isquared x R.

Of course the topic has drifted into this problem of superposition which has been approached before along similar lines. The truth of the matter in the thin film discussion is that it doesn't require a complete solution of either electric fields or power to realize that "total cancellation" of the waves described in the example is impossible.

It is quite evident that through the actions of the first interface, that there is less energy incident upon the second interface. Further, given that both interfaces operate with identical reflective and transmissive properties, it follows the second interface could not reflect enough to totally negate the reflections of the first.

Torr had a question in this regard, but as he is a casual correspondent we have not seen any further comment from him - nor would I expect him to have amplified on your observation above.

Your loop is sensitive to magnetic fields, such as might be produced by the horizontal deflection system of a Television set or computer monitor, or by a switching supply in a computer. The best way to minimize that problem is to orient the loop to null out the interference. An additional way is to move the loop as far away from likely sources of interference as possible. Power the antenna and R75 from a car battery or portable DC source and take them outside and roam around to see if you can find out where the noise is coming from.

Mark:

I have NEVER owned such a loop, and frankly, can't comment on its exact workings.

However, the others seem to be suggesting, switch radio and loop to battery power. Is the noise gone? If so, you have localized your problem. If not...

Shut off everything in the home (building, business, etc), is the noise gone?

If so, turn on things one at a time and locate the interference.

Frankly, I suspect I am wasting my text here, and you have already done this...

My brother quit the power company when they were switching to "underground utilities" - he got tired of burying those telephone poles so deep! And I had to give up chicken farming because the county extension agent said I was planting them too deep - I think I must have been planting them too near the underground power lines.

Sometimes it works if you unplug it, turn the plug 180 degrees, and plug it back in.
ground loops get hairy sometimes.

> ----
> Reg.

Hi Reg, I live in the Great City of Birmingham, and there was no tornado yesterday due to Earth warming climatic changes caused by American pollution of the atmosphere. We do have tornados here from time to time and have even before the American pollution of the atmosphere.
Of course I live in B'ham Alabama USA so I am closer to the pollution than you are. The company I work for has spent billions on environmental projects as has a number of other companies. It is starting to make a big difference in the air quality over here. I doubt seriously the B'ham tornado was anything out of the ordinary (1 every 100 years).
If you want to see who is really cranking out the pollution, look at third world countries who are attempting to progress, which takes energy that they can not afford, much less any pollution control. China comes to mind.

Draw a transistor (FET, or triode) with a capacitor from collector
(drain, plate) to emitter (source, cathode), an inductor from
collector to base (gate, grid), and a capacitor from base to emitter.

Ground the emitter and everything connected to it and take the output
from the collector. You have a Pierce. Replace the inductor with a
crystal and you have a Pierce oscillator with the crystal operating in
the anti-resonant mode.

Ground the collector and everything connected to it and take the
output from the emitter. You have a Colpitts. Replace the inductor
with a crystal and you have a Colpitts oscillator with the crystal
operating in the anti-resonant mode.

Insert a crystal between the emitter and the two capacitors connected
to it and take the output from the emitter and you have a crystal
oscillator operating at series (or overtone) resonance.

Stick a varactor in there someplace and you have a VCO or VCXO.

Clapp, Vacker, Franklin, Butler.... they are all just variations on an
old theme.

Wes:

Of course there are millions, if not billions of 'em in my computer, encased in the chips there, but having viewed many, many spec sheets and diagrams of the internal geometry of the chips, can't say I would really bet there is a colpitts commanding the freq of the bus in my computer, nor the daughter boards in their...

Now you might be right, it is just an argument I must defer from, since reliable data one way or another cannot be obtained without expending more effort than I am prepared to expend... I'll even grant you a win by default--the argument simply is not deserving of my time, and anyone with access to the internet can look at a diagram depicting components used in the clocks of "modern circuits."

This has been done since the beginning of radio. Nothing new. However, I am interested in the sand antenna. I would love to hear more about working antennas that exist entirely below ground. I am guessing but would say this would not work on any band above 160 meters. I know the Navy has made huge underground radiators at frequencies like 50 khz. I would be surprised to hear that something as high as 1.8 mhz could be made to work.

Nunya, you are so focused on a rule for the sake of an archaic rule that I wonder why you don't ride a horse, donkey or camel as your primary transportation. That way you never have to upgrade your thinking to include motor vehicles.

If you are reading this thread from the beginning, TOP DOWN, you are scrolling through hundreds of line of comments to find new comments. Never mind your wasted time. Think about the wasted bandwidth!!

Get with the changes that are happening. Bandwidth is a limited resource. TOP POST when and where appropriate.

BTW, vulgarity never wins an argument or establishes a well thought out point. Vulgarity causes people to form an opinion of you that is not in your best interest. Your use of vulgarity drags you to the gutter and many people simply turn you OFF.

True for any one reflection. But as an optical engineer I'm sure you're aware that, even in a lossy medium, a given wave reflects back and forth multiple times before it's amplitude is reduced to insignificance. As you know, the measured amplitude at a surface would then be the superposition of multiple successively reflected waves.

So says JM Vaughn in his book "The Fabry-Perot Interfermeter". He cites Born and Wolf a lot. Also Kuhn, Steel, Liddell, Mcleod, Meissner, Tolansky, Jacquinot, and of course, Fabry and Perot. Strangely, no mention of Hecht.

For those who are interested, a Fabry-Perot interferometer is an optical instrument comprising two partially reflective parallel mirror surfaces separated by some fixed or variable distance. It's basically a narrow-bandpass filter at light wavelengths.

Strawman Alert!!! Richard H. did NOT say power superposes.
It is obvious that what he was disagreeing with was the
statement: "You CANNOT ... even talk about the "power"
of various reflections in the same media."

I recall reading some years ago about underground antenna experiments done by the military. I believe the were done well into the HF range. A trench was dug, the antenna put into the trench but not in direct contact with the soil, then the top was covered. The objective was to make a concealed antenna for relatively short range communication. The signals were much weaker than for an above-ground antenna (~30 dB if I recall correctly, but I might not), but still usable for the purpose at hand. This shouldn't be surprising.

On the contrary, it is quite evident that through the actions of the first interface, namely reflection and wave cancellation, that there is *MORE* energy incident upon the second interface. Here's the example from my earlier posting. Those who can, please calculate the forward power in the 1/4WL 100 ohm section. Who believes, like Richard C., that it cannot possibly be 100 watts or more?

100W 1/4WL
XMTR---50 ohm---+--------100 ohm---------+---200 ohm---200 load
feedline A feedline B feedline

Well, there is usually only one oscillator, not billions, and I'm sure
that I said "Pierce", not Colpitts.

I just did a little "data mining." Out of the last 188 posts in this
forum, you made 47 of them, or 25%. Perhaps if you "expended some of
the effort" that you waste writing every fourth post you would have a
little time to actually research what you're saying -before- you write
about it. Just a thought.

BTW, I wasn't trying to "win", I was trying to correct the insane idea
that knowledge of "old time" oscillators is unworthy of study when
talking about "modern" radios. The fact that this belief exists is
proof positive that questions about these things should remain in the
amateur exams. But expending effort to learn the basics is too much
effort for "modern" hams.

Plus the applicant's self-esteem might suffer if he has to gain a
little knowledge of electronics, antennas, transmission lines, good
operating practice and Morse code, so I suppose the FCC should just
issue licenses to anyone who makes a request.

I'm not arguing with you but as with all words, it depends upon how
one defines "power". You have your own personal narrow definition.
The power industry has a different definition.
Even the field of RF engineering has a definition of power
different from yours. The IEEE Dictionary has 11 pages of definitions
dealing with power including the "power reflection coefficient",
"power density of a traveling wave", "radiated power", "power-flow
vector", "power transfer", "power 'carried' by a waveguide" ...

Why don't you visit your local power company, call a meeting of their
engineers, and inform them that there is no power flowing in their
transmission lines? :-)

Wes:

On promptness of my responses...
(I am truly flattered my posts are worthy of such analysis on your part! I would never have bothered gathering the statistics!)
I wrote a c++ utility/plug-in for outlook express, if I mark someone as being of interest to me, when they post I am immediately notified with a small icon and an audible alarm is given, if I click on the icon I can read their post and begin a response immediately--if desired...

Now, don't go to thinking you are special, however, when your posts turn interesting (or adversarial <grin>) I mark you (you are a "marked man" during those times! <grin>)...

I have other tricks too... however, be warned, I consider this to be only a newsgroup, my posts, indeed, everyone else's posts too, are just NOT that important as some things in life... quick responses which may, or may not, be well thought out are quickly typed and sent--I go back to what I was doing...

Don't get me wrong though, a person is as likely to come upon a nugget of knowledge here, as anywhere, I suppose... anyway, there is a real "enjoyment factor" which exits here, that is why we are here--isn't it?

Frankly, it is a bit of a hobby, just one a guy can do while doing a load of other things...

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <11elvqvgjrhpk5c@corp.supernews.com>
Source record: 72470

Fred W4JLE wrote:
> You might be interested in the 1918 article on underground antennas.
> http://www.rexresearch.com/rogers/1rogers.htm

Thanks for the reference. A key observation from it is:

"One of the Naval experts present mentioned that it had been found that the penetration of the ground wave component increases with an increase in wavelength. This is an important fact and helps to explain the operation of this new radio system, with its aerials buried in the ground."

I believe this method is still being used for communications to submarines. It depends heavily on the very great skin depth and relatively low attenuation in sea water at the VLF wavelengths used.

The buried antennas I was referring to operate, as far as I know, with normal field propagation through the air, not through the ground.

Here are the skin depth in feet and attenuation per foot in salt water:

Freq Skin Depth Atten
ft dB per ft

10 MHz 0.23 37
1 MHz 0.73 12
100 kHz 2.3 3.7
10 kHz 7.4 1.2
1 kHz 23 0.37
100 Hz 74 0.12

And here they are for average ground:

Freq Skin Depth Atten
ft dB per ft

10 MHz 13 0.66
1 MHz 25 0.34
100 kHz 74 0.12
10 kHz 230 0.037
1 kHz 738 0.012
100 Hz 2300 0.0037

So communication through the ground or even salt water is practical at low frequencies. High frequency is another matter, though. But that doesn't preclude using buried antennas for sky wave propagation.

My guess as to the date could easily be that far off. But if your friend wrote it for QST or HR, he used a pseudonym -- I don't see his call or name in the inclusive indexes of either magazine.

It must have been in CQ or 73. I can still recall the diagram, showing the buried antenna and the dotted "image" above ground.

Jim Kelley wrote:
"That`s because power doesn`t propagate, and hasten to add - neither do Poynting vectors."

Words are not objects. They merely represent objects. We use abstractions for brevity and clarity. Even the best say: "--the Poynting vector or power density (watts per square meter)." See Kraus` 3rd edition of "Antennas" page 73, under "Power Patterns".

Best regards, Richard Harrison, KB5WZI

It's important to me. Let's just settle on -- I'll top-post
and move on; you can just ignore the first few lines and read to the
bottom, then scroll back up to the top to find the really good stuff.

Not always, but I just opened a book last week to around page
89. It was a hell of a good read, so I found it worth going back to
restart at page one. :-)

I also rotate around among three to five books I'm reading
simultaneously.

I rarely see those -- they usually appear at the end of a
properly-formatted bottom post, right after the original 235-line
posting.

By the way, not to be a spelling Nazi, but if you're going to
appear oh so proper and pompous, you really should look up the
singular of criteria for when (as above) its the correct word.

Or ploughed.

One thing that top-posters fail to recognise is that not all ng users
set their readers to order posts by thread. It is quite possible, with
a suitable newsreader, to order posts by time and date, rather than
subject.

Unfortunately, those who merely bang the Reply key to top-post their
answer frequently have the point to which they are replying way off
the bottom of the screen, which it is not immediately obvious without
scrolling down.

Top-posting also encorages the lazy or incompetent to avoid properly
trimming their posts.

There are even those who used to trim and bottom-post who now top-post
exclusively, but who quote the RFC as if it is some religious mantra
in some form of self-justification.

>True for any one reflection.

Hi Jim,

And true for ALL accumulated reflections there after. Reflections do
not add any energy to the cup when the first interface is draining it
more quickly.

>But as an optical engineer I'm sure you're
>aware that, even in a lossy medium, a given wave reflects back and forth
>multiple times before it's amplitude is reduced to insignificance. As
>you know, the measured amplitude at a surface would then be the
>superposition of multiple successively reflected waves.

My analysis allowed ALL of the energy in the reflection from the
second interface (0.098X) to combine with the first reflection
(0.11X). This total superposition was both more than generous, and at
the same time very unlikely; and yet with this generous allowance
there is still excess reflection from the first interface. Hence for
something less than total superposition of ALL energies, it hardly
bodes a better yield in total cancellation - the energy just isn't
there in the first place. 0.098X <> 0.11X is the simple economics of
the balance.

As an optical engineer, I've dealt with the harsh reality of this myth
of total reflection cancellation. I've designed systems with 9 orders
of dynamic range and the couple of percent dashed off as being
invisible by academics was distinctly and overwhelmingly present.
Basically I had the advantage in fluorescence measurement in being
able to turn off my detector during the initial flash to suppress the
reflection products in time rather than in these shenanigans (I did
them too - and certainly much more - because even the detector can be
blinded in its "off" state).

Basically these claims are for first year students where demanding too
much inquiry would push them into switching majors to Business school.
Simple optics with simple, ordinary glasses exhibit quite useful
results, but they do not embody a proof. To anyone following the math

of my presentation, it is quite obvious what WOULD tend towards a more complete cancellation - and such a subtle shift in the formula diverges only slightly from the choir book hymn. It's not that hard when the interface ratios drive the answer.

How many oscillators are there if you include quantum oscillators? :-)

If we send a pulse of energy down a transmission line, one
wonders where the power in the pulse is if not in the pulse.

> more quickly.

If the first interface is a Z0-match, it is not "draining it"
at all. That's what you are missing. The examples have been
for matched systems. If you change your medium 3 to an index
of refraction of 4.0 instead of 4.04, your example is *perfectly
matched* and the first interface is NOT draining the system
because all reflections are canceled. 100% of the source power
is being delivered through the first interface because of that
wave cancellation. At that point it is being joined by the
reflected power so the forward power in the second medium is
greater than the source power. In the second medium, forward
power equals source power plus reflected power. In your example,
source power is one watt, forward power in the second medium is
1.125 watt, and reflected power in the second medium is 0.125 watt.

> My analysis allowed ALL of the energy in the reflection from the
> second interface (0.098X) to combine with the first reflection
> (0.11X). This total superposition ...

Power cannot be superposed. If you are going to deal with power,
you need to use the interference equations for power calculations.
Or alternately, convert the powers to voltages, superpose the
voltages, and then calculate the power from the superposed voltage.
That's what most RF engineers do and it works well.

> As an optical engineer, I've dealt with the harsh reality of this myth
> of total reflection cancellation.

Since you don't understand the physics, it is no wonder that you
failed to accomplish total reflection cancellation. And total
reflection cancellation is easier to accomplish in a transmission
line than it is with light in air.

He may have used a pseudonym. He did prefer to write for CQ, they paid
a little bit where QST did (does?) not. I have been out of touch with
Bill since leaving the Central Ohio area.

As I recall, after he had one such artical published he received quite
a few letters from people who took it seriously.

Back in the day, we received traffic from the station in Jim Creek while submerged. They used a 13 mile array strung between 2 mountains. IIRC it was on 18KC. CW only as any frequency shift would have put the finals out of resonance. Much better methods today that remain classified.

I know we could receive it when submerged in the Red Sea.

Single (first) reflection only.

> This total superposition was both more than generous, and at
> the same time very unlikely; and yet with this generous allowance
> there is still excess reflection from the first interface.

Your generosity is hardly the issue. Previously reflections are more to
the point.

Hi Jim,

As the total energy returning from the second interface is 0.098X, not
0.11X, and not even all of that passes through the back of the first
interface, where do you come up with the remaining difference to
accomplish a complete cancellation?

Even if an infinite summation of ALL reflections kept any energy from
transiting the second interface (a generous allowance not likely to be
observed anywhere), then it cannot exceed what energy was initially
introduced into the system. With that generous allowance, the
infinite summation can only equal 0.098X which remains less than the
reflection from the first interface of 0.11X. Without that generous
allowance, it must be something less, which can only increase the
total, uncancelled reflection product. Either way, "total
cancellation" is not total.

Does not apply. Earlier I said, "All sine wave oscillators, LC or
crystal, are basically the same circuit with the only variable being
the location of the rf common point."

These are not LC or crystal oscillators. The only place you might
find one of these in a modern radio is in the sidetone oscillator.

Roy. as you know, radio propagation through the ground follows exactly the same laws as propagation through anything else.

All is governed by the resistivity, permeability and permittivity of the medium, at a partcular frequency, and the geometry of the interfaces between different mediums.

The problem of finding solutions to paricular problems lies only in entering input data into a general purpose, number crunching computer program, which I'm sure versions of it already exist.

Don't be so anal-retentive. There will always be those who insist on
top-posting. If you don't like it, don't read their posts. You'll be
missing about half of the posts on usenet, but then we won't have to read
your repeated whinery about top-posters.

Sure. The only real differences among salt water, dirt, and air are the loss -- which is a big difference -- and propagation velocity.

NEC-4 can handle antennas and propagation in two media of infinite extent separated by an infinite plane boundary. Neither one has to be air. While this doesn't imitate some real situations very well, it can produce some good insights into propagation and the performance of antennas embedded in a medium other than air.

I've seen power engineers with clipboards and hardhats. Their
title is "Power Engineer". What will they think when you tell
them that power generators don't generate power, power transmission
lines don't transfer power, and power meters don't meter power?
They may all end up in a white coat because of you.

The rest of the world simply does not share your definition of
"power". Did you see my question? If the power associated with
an EM pulse is not in the pulse, where is it? A power meter
registers power during the pulse but nothing before and after
the pulse. The power was there during the pulse. Where was it
before the pulse arrived? Where did it go after the pulse left?

3755. 40 meters added to 5-band Yagi without increasing size or weight

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-31 02:42:18 UTC
From: Chuck Olson <chuckolson01@REMOVETHIScomcast.net>
Message-ID: <w6adnceHF_g9p3HfRVn-sg@comcast.com>

If you haven't read about the "SPIDERBEAM" yet in QST for July 2005, you might want to check out a copy from the library, or join the "spiderbeam" Yahoo! group and read about the latest developments. The kit comes out of Germany www.spiderbeam.net , and is sold in the U.S. by www.thewireman.com .

So what's this about adding 40 meters? Let's take the basic 3-band Spiderbeam - - 3 elements on 20m, 3 elements on 15m and 4 elements on 10m - - no traps - - nice, huh? It turns out since everything is made of wire strung between fiberglass poles, we can connect the center of the 20m director to the center of the 20m reflector with a wire about 10m long and the overall result is a dipole with V-shaped capacitive hats at each end, resonant at about 6500 KHz. At 7150 KHz, the dipole has a measured inductive reactance of about 171 ohms, courtesy of my MFJ-260 Antenna Analyzer, and it would need about 130pf in series to resonate it. A balanced feed would require two 260pf capacitors. The manufacturer who discovered this resonance felt it best to connect the dipole to the center support plate to ground the center and feed the dipole with a "Gamma Match" configuration to control the feeding resistance at resonance. Further investigation kept the center ground but changed the feed to a balanced "Delta Match" to be compatible with the balanced feed to all the other band antennas. So that's it - - 40 meter dipole - - no increase in size, only by adding a total of 14 meter of bare wire - - one 50 ohm feed through a current balun - - 4 bands.

The Spiderbeam is also available in a 5 band kit adding 2 elements on 17m and 2 elements on 12m, which becomes a 6 band antenna with the 40m dipole. And the required 250pf 15KV capacitors (for full power operation) can be mounted in the weatherproof balun box, with two added terminals for the Delta Match wires. I found 6KV capacitors locally which seem to work okay with my rig's 200 watt maximum output.

Okay, so the added wire adds a little weight, but it's small. Enjoy!

73, Chuck W6PKP

> As the total energy returning from the second interface is 0.098X, not
> 0.11X, ...

The total energy returning from the second interface is 0.125 watts.
Your solution is incorrect. Why don't you take a poll to see who
agrees with you?

> Even if an infinite summation of ALL reflections kept any energy from
> transiting the second interface (a generous allowance not likely to be
> observed anywhere), then it cannot exceed what energy was initially
> introduced into the system.

It cannot exceed the energy. It can certainly exceed the steady-state
source power (joules/sec) and it does. Some energy is sourced during
the transient stage that does not reach the load. It is stored in the
second medium as standing waves. The forward power in the first medium
is one watt with no reflections. The forward power in the second medium
is 1.125 watts. The reflected power in the second medium is 0.125 watts.
The forward power in the third medium is one watt with no reflections.

Have you never seen the forward power in a transmission line exceed
the source power? If the system is Z0-matched and the SWR on a
1/4WL transformer is 5.83:1, the steady-state forward power on the
1/4WL transformer is *double* the steady-state source power.

> Either way, "total cancellation" is not total.

In your n=1,2,4 example, reflected wave cancellation is total in
medium 1 (assuming a lossless system). If n2=sqrt(n1*n3), the
reflected wave cancellation is total.

Hi Group,

I have a pi-network, or at least I believe it is a pi-network in my antenna tuner. It has two caps to ground and one in series inductor.

If I tune my SWR for 1:1 and go back and measure each value of the capacitors and inductor, is there a equation or computer program I can use these measured values to obtain my complex impedance at the input of the coax cable?

Arn't you going around your hindparts to get to your elbow?

Connect an MFJ259B or similar and measure at the coax.

Once these valuses are measured at the frequency of interest, you can determine from the tuners specs if you will be able to achieve a match. If you can already achieve a match isn't determining the value simply a neat mental exercise?

You ought to be able to do it from first principles, the computation
is not that difficult.

Some of the issues include your estimate of the value of the
capacitors, the value of inductance, and the Q of the inductor. You
could try to form a value for those by substitution of some known
capacitors and "matching up" a known load, working back to estimate C,
L, then use those values to solve the unknown case. The accumulated
error might render the answer of little value.

One program that springs to mind that solves a pi network is in the
Hamcalc suite, but IIRC, it treats all components as ideal (ie
lossless). Reg Edwards has another that you could play with, and IIRC,
it does allow you to specify unloaded Q of the inductor.

Have a play, you have nothing to lose and everything to learn!

Owen

Hi OM,

Good time to learn the Smith Chart. The components in that network
are simply arcs moving the presented Z to the transformed Z (50Ohms).
Unfortunately this is easier said than done - or understood. Like all
skills, time and practice are necessary.

As for understanding, the Smith Chart will bring that quicker than any
software - which simply dumps an answer in your lap, the quality or
actual utility of which is as much a mystery as the problem you wanted
to solve. There are a multitude of network settings that will satisfy
the matching and software or equations will do little more than say
"yup, that setting does exactly as you observed." Not very filling,
but when you do the same thing on the Chart, you can see where you are
going before you get there. This means you also have the choice of
choosing the best path (shortest). It would be a rare piece of code
that could do that - from a mountain of formulas.

Just a followup on my original post under this subject.

I completed my short 75M dipole (Inverted V) and am very pleased with it.

Went to the hardware store, bought a piece of cheap bathroom plumbing material, 1.5" diameter and very light. (Lighter than PVC)

Bought some #18 stranded hookup wire.

Found an old spool of Telephone indoor station wire (#22).

I wound my 1.5" dia coils with the telephone station wire. Worked very well. I wanted a 50 uH coil so as it turned out, 50 turns, close spaced, did the job. (about 25 turns per inch).

I positioned the coils about 6/10 of the distance down my dipole legs; the total length of each leg came out to 24 feet. The feedpoint is at the top of my 23 foot cheap telescopic RV flag pole. This antenna tuned right up to freq... 3950KHz in my case. SWR was about 1.6. Seems usable between 3900 and 4000. If I want to go lower, I just hang a couple alligator clips with 6" wire off the ends to lower resonance.

Project was easy, and whole thing is light, small, easy to erect, and works well, considering size. Works well with my FT-817.

Thanks to those who made replies to my post.

I would caution you in regard to measuring the values of the C's and
the L of your pi network. If you actually have an RF bridge or other
test equipment suitable for accurately making such measurements, you
are indeed lucky. Even with such equipment, you should realize that
you will have to disconnect certain components from one another in the
tuner in order to actually make the measurements on each of the three
components. You are also probably going to have to remove some of
those components entirely in order to make the measurements with
reasonably short leads. For anything below 10 MHz, the lead length
will not be a significant factor.

Assuming that you are successful in making the measurements with good
accuracy, the necessary calculations require a good knowledge of
complex numbers and complex arithmetic - much of which is adequately
explained in the Amateur Radio Handbook.

My suggestion at that point would be to simply post your results,
including the frequency of measurement, to this forum and request that
one of us make the calculations for you. I'm sure many, including
myself, would be glad to do that for you. It's the quickest way, by
far.

If he has an RF bridge, couldn't he simply terminate the tuner's input
with 50 ohms resistive and measure the impedance at the tuner's output?
Well, the conjugate, anyway. I'm trying to imagine the benefit of doing
it that way, rather than simply measuring the impedance at the
transmission line directly.

Chuck,

Richard, in addition to Ridenour, I quote from Reflections 1 and 2, Chapter 8, "A semantic problem with the term "power flow" also fuels the erroneous belief that reflected power is fictitious. This brings us to the question, "Does power flow?" To help us understand the answer, let's examine an analogy that involves current.
When we talk about "current flow," we take the meaning for granted. However, does current really flow? The basic electricity sections of engineering textbooks (also The ARRL Handbook) say that current does not flow--charge flows. Current is defined as the quantity of charge flowing past a point per unit time. However, once we leave basic electricity and move on to circuit analysis, the term "current flow" is used almost exclusively--and
yet we know exactly what is meant.
The same problem exists with the term "power flow." Engineering textbooks define power as the "quantity of energy passing a point per unit time." Thus, power does not flow--energy flows. However, except when reciting the definition of power, textbooks and journals on wave propagation use the term "power flow" almost exclusively, with only an occasional use of "energy flow." As with "current flow," we know what is meant because of the common usage which generally overshadows the strict definition."
Perhaps this explanation will satisfy Jim, but perhaps not. We'll see.

What virtually every engineer means when he says, "power flow",
is, "the power (energy per unit-time) associated with the energy
flow". Knowing Jim, he would also probably argue that the sun
doesn't rise - that instead, the earth rotates. However, most
weather forcasts on TV gives the times for sunrise and sunset.

Cecil, W5DXP wrote:
"What is it about, "...all "lost" reflected intensity will appear as enhanced intensity in the transmitted beam." that you guys don`t understand?"

A quarter-wave intermediate impedance line section can perfectly match different resistances at its ends.

When a match exists at the end of a line, there is no discontinuity and the line appears as if infinite. There is no reflection from an impedance match.

It`s a multiplicity of waves which seem gratuitous.

Amen brother!

Hi Richard,

This statement you respond to is one of those attempts to draw the topic away from its focus to prove another point of match which humorously was going to be proven with the original topic.

Now, if that sounds confusing, it is simply par for the course in how we got here. And to extend the metaphor for par, we started out Bowling for Dollars and have now ended up putting on the back nine.

Anyway, the optical analogue has proven to be a bust when I demonstrated that reflection products do persist. This is not the place to hash over that again. If you wish, you can consult my original posting and the follow-ons for details.

There's nothing wrong with calculating the power per unit area at any point in a transmission line. I'm sorry if I gave some other impression. The problem I have is with believing that the calculated value propagates as if it were an electromagnetic field. The Poynting vector is useful for making calculations, but it not a useful tool for explaining the behavior of natural phenomenon.

Walt, W2DU wrote:
"A semantic problem with the term "Power Flow" also fuels the erroneous belief that reflected power is fictitious."

Another world-class expert has agreed that power flows.

Energy may or may not flow. It is the accumulation of flows that you pay for on your monthly electric bill. Power is the rate of delivering energy (doing wotk), so it can`t stand still. No power flow, no work.

Take it from W2DU. Reflections are important. Reflections occur at discontinuities.

To the extent that voltage and current are in-phase, they mean real power. Zo is resistive in a practical r-f transmission line. Incident and reflected waves both propagate on the line with their individual voltages and currents locked in-phase. The sum of incident and reflected waves can`t be relied upon to indicate power, but infividually each wave can indicate true power.

The reflected wave interferes with the incident wave to produce standing waves. These represent the impedance distribution along the line. They do not represent variation of power in the wave in eather direction.

I have an MFJ-269 which I can measure the input to the coax and get a direct impedance measurement.

Then I would put the tuner in line with the MFJ-269 as the source and adjust the tuner until I see 50 + j0 on the MFJ.

I would follow by measuring the pi-network components also using the MFJ as it will measure values at the desired RF frequency.

I would keep the signal frequency low so that stray inductance and capacitance do not affect the measurement.

What I would like to do is see by using the values I obtain, calculate the cable load and compare with MFJ direct measurement.

I will review the handbook to see if there is a standard equation knowing the values and assume that the Q of the inductor is greater than 10.

All in the fun of the hobby.

3777. need help understanding this broad band antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-01 18:49:32 UTC
From: larry <larya@rogers.com>
Message-ID: <-M6dnXhJ4bWj8nPfRVn-qg@rogers.com>
Source record: 72393

Greetings

I have been reading about this new? broadband antenna... It seems mainly used in the short wave receiver domain but I also find newly licenced amateur also using it...

It is a spin-off of the 'end fed' antenna but seems to have some point blurred in the translation.....

The antenna is constructed as follows....

A random length of wire any where from 40 feet to 140 feet.. The end nearest the house is connected to one end of the high impedance end of a 9 to1 balun.. The other end of this end of the balun is connnected to ground...

The arguement is that because the high impedance end is connected to ground that the antenna is quieter...less noise...

The low impedance end of the balun is connected, via a length of 50 ohm cable, to the receiver... or transceiver...

The other end of the cable is connecte to the receiver or transceiver and needs to use an antenna coupler.....

My question.. is this a valid antenna....

Personally, I don't think so...

I beleive that because the antenna comes to the radio in 50 ohm coad but still needs an antenna coupler the swr must be high therefore the antenna in not valid...

Someone suggested that this design is a spin-off of an end fed dipole or zepp ...but I disagree...I think there are a few points missing for it to qualify as an end fed dipole or zepp...

Larry ve3fxq

anyways.. any thoughts?...

Hi Larry,

An antenna coupler for either SWL or Ham use is distinctly indicated
for this "broad band" antenna. It is only broad band if it can be
distinctly used across a broad band (this maybe someone's idea of 5KHz
or 50MHz).

>Someone suggested that this design is a spin-off of an end fed dipole or
>zepp ...but I disagree...I think there are a few points missing for it to
>qualify as an end fed dipole or zepp...

Well, shy a few points is not distinctive enough to dismiss the design
from the end fed dipole or Zepp categories. Suffice it to say that at
some frequencies, and with the right matching, you could not
distinguish this antenna from them (insofar as results go).

That's a worthwhile educational exercise.

You might find a single equation, but it gets a bit messy. However, it's easily done in a few steps, if you're comfortable with complex arithmetic. I use an HP48GX calculator for this sort of thing, since it readily and directly handles complex numbers.

Call the capacitor on the input side of the network C1 and the on the output side C2, and the inductor L. First calculate the reactance of each of them at the frequency of interest, Xc1, Xl, and Xc2. You'll find formulas for those in the Handbook. Note that Xc1 and Xc2 will be negative and Xl will be positive.

First calculate the parallel combination of the load impedance (Zl) and Xc2. That will be the impedance seen looking toward the load from the output side of the inductor: Za = Zl || Xc2 = (Rl + jXl) || (jXc2), where Xc2 is negative. The combined impedance of two impedances Z1 and Z2 in parallel are 1 / ((1/Z1) + (1/Z2)) = (Z1 * Z2) / (Z1 + Z2).

Now add Xl to your result to find the Z looking into the input side of the inductor: Zb = Za + jXl. (If the inductor has appreciable loss, use Zl = Rl + jXl instead of just jXl.) Finally, calculate the parallel combination of that impedance and the impedance of the input capacitor to find the impedance looking into the network: Zin = Zb || jXc1, remembering that Xc1 will be negative.

You can of course combine all this into one equation, but it gets pretty big. I prefer to do it in steps, one of the reasons being that I understand exactly what I'm doing at each step rather than just dumping numbers into an equation and hoping that what comes out is right. A Smith Chart gives you an even better feel for what's going on, and this would be a good opportunity to get acquainted with that valuable tool. You might solve the problem both arithmetically and by using the Smith Chart and compare results.

If you aren't comfortable with complex arithmetic, the equations get considerably more complicated since you'll have to deal with the resistance and reactance separately. If that's the case, I second the advice already given that you either solve it using a Smith Chart or consider just letting one of the other folks on this group do the calculation for you.

Anyone here using the MA-5B? I'm running a 360ft loop at 60 feet now (thru a tuner) and I'd like to get something more directional for DX. I was told by others that a vertical would be good for DX but I had an MFJ vertical before and I wasn't too fond of it. 15, 17 and 20M are my bands of choice.

A 7ft boom with the longest element around 17ft. For a small beam, is this a good choice?

Greetings to you Larry,

Any length of wire is a 'valid' antenna. i.e., it is sure to work.

If it's a short wire it will have sharply resonant frequencies and will not be broadband.

If it's long enough, and its normal attenuation is high enough, it behaves as a transmission line and its input impedance will eventualy converge on the line Zo. Depending on height above ground, on wire diameter, and on the general environment, Zo will be roughly resistive between 500 and 600 ohms.

You then have your wideband antenna. A 9-to-1 matching transformer reduces the impedance to about 60 ohms which is very nicely between 50 and 75 ohms. So you can take your pick of what impedance receiver you use.

If the antenna is not very long in terms of wavelengths, or even if it is, it can be terminated, at the remote end, to ground with a 560-ohm resistor and then the antenna will have an input impedance of about 560 ohms all the way from DC up to many, many MHz. Which is wideband enough to keep everybody happy.

Unfortunately the antenna's radiation pattern is many-lobed in the direction of the wire. When terminated it is highly uni-directional which is unlikely to be of much use to most people. It will nearly always be in the wrong direction. Which is why it is not very popular except for static, specialised, point-to-point LF communications.

It's really quite simple. Try not to be distracted by over-complicating experts on reflected and non-reflected power and standing waves.

Actually there is a name for such a wideband antenna. But I can't think of it at the moment. It may be the early symptoms of Alzeimers.

Where did you read about this antenna ?
Receivers can withstand a lot more swr than transmitters, so it should work fine for swl.
Compared to< no antenna>, its great.
It might work better if you had an antenna tuner between the antenna and the radio.

I will break my own rule of not responding to responders and answer
your question - otherwise you would assume that I was ignoring you.

If I might answer a question with a question - why do you think that a
tuner would give up its settings so easily? It's a an interesting
speculation. First, let me clarify what I mean by a Tuner's input
terminal and its output terminal. Considering that a tuner handles
transmitted power in one direction only, we should refer to its
"input" side as the port that connects to the transmitter and its
"output" port as the one connecting to the antenna or feedline.

That agrees with what I interpret your post as suggesting. Therefore,
a 50 ohm termination at the "input" side "should" produce a measured
impedance at the "output" port that is, as you say, the complex
conjugate of the impedance seen looking into the transmission line. I
haven't done a rigorous analysis of that configuration, but it
certainly seems reasonable and correct. It would, indeed be an optimum
way of inferring the impedance that the original poster is trying to
measure.

I see nothing wrong with your suggestion and would recommend it.

I also see no reason to do any of that as it would be just as easy to
measure the transmission line input impedance directly - as you said.

It's amazing how much good stuff comes out of the woodwork when people
are interested in their hobby and interested in learning.

Thanks,

Cecil Moore wrote:

> If the power associated with
> an EM pulse is not in the pulse, where is it?

According to definition, the 'effect' of power is something which can be realized at a place where energy either is being transferred from, or transferred to. The amount of effect is proportional to the rate at which energy is transfered. But power is not the thing which is being transferred from one place to another. Often times though we want to know the rate at which energy is being transferred to or from one place to another, and there are mechanisms we can use to measure things that manifest themselves in proportion to that quantity. But some folks forget that it's just a tool for making accurate predictions about things, and start to believe some odd things about the behavior of nature. One must be careful not to mistake a physical quantity for a physical entity.

If the tuner can cope, there's not much interest in what the input impedance of the transmission line is.

What IS of interest is what impedance terminates the remote end of the transmission line. Usually this is the antenna. And usually this is impractical to measure directly.

From the input impedance of the transmission line, Program ZL_ZIN computes the input impedance of the antenna (or whatever may be at the other end). It is also necessary to know the length of the line and its Zo.

Download in a few seconds program ZL_ZIN from website below and run immediately,

Hi Walt,

I am familiar with the common usage of the expression 'power flow' and of course the Poynting vector. I've been explaining that "energy flows - not power" on this newsgroup for 4 years and have gotten nothing but grief for it. I think it will be more interesting to see whether your explanation will satisfy the others.

With sufficient accuracy, knowing its maximum value, it is possible to estimate the value of an air-spaced variable capacitor setting just by looking at it.

Similarly, the value of a coil can be calculated by counting the number of turns and guessing its length and diameter. The calculation is simple enough.

I've done it dozens of times. It gets you into the right ballpark. Which is quite accurate enough for amateur radio purposes. There's no need for rocket science.

I can't understand the abysmal state of education in simple arithmetic in our primary schools. We should import the kids who inhabit the sewers of Rio de Janerio and other American cities and employ them as arithmetic teachers. It would be more economic than culling by armed police.

Let's pretend that the antenna (load) Z = 49 +j0. Let's also pretend that the "tuner" consists of a series 1 ohm resistor.

Looking into the input of the "tuner" we measure 50 +j0. Pretty good, huh?

Terminating the input of the tuner with 50 +j0 and looking from the other end we measure 51 +j0. Whoops.

Best have a lossless tuner to play this game.

I credit the California and Oklahoma Public Schools for my mathematical
illiteracy. Went to school in Bakersfield in 1947, got straight A cause the
math they taught in the 9th grade was the math I learned in Oklahoma in the
4th grade. Returned to Oklahoma in the middle of the school year and was
placed in a 2nd semester
Algebra class. Teacher was a coach who spent most of his class time working
with (on?) a female student whom he later married. Even if I had been truly
interested I'd never have been able to catch up. I was passed on even though
I was totally incompetent in Algebra.(this was before social passing became
common in the public schools)They should have adjusted my schedule and had
me start at the beginning Algebra semester even if it required some class
juggling the following year. Perhaps they thought they were doing me a
favor, or maybe they just didn't realize how retro the California school
math was.

3793. How Handle Multiple Open Wire Lines?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-02 00:43:34 UTC
From: greg knapp 5 <gknapp@freshrain.org>
Message-ID: <xMSdnQsEIcAoXHPfRVn-3Q@speakeasy.net>
Source record: 72409

I need your advice, as I have never worked with open wire lines before.
I need to feed many different antennas with open wire line and need to run the feeline from each about 200 feet from the back pasture to the shack. I don't want to walk out 200 feet and throw knife switches to chose the antenna/feedline I want to feed, so I plan to run separate 600 ohm open feeds for each antenna all the way to the shack.
The problem is I don't know what the effect is or how to handle the multiple open wire feed lines, as they will be parallel for probably 150-200 feet. I haven't found anything in literature describing this.
For instance, will they interact? how far do you space the feedlines from one another? If I have 4 feedlines, can I stack them vertically or horizontally one foot apart from each other? How much is enough separation? What other precautions do I need? Need they be twisted if they are not near anything other than the other feed lines?
Any help is appreciated.

One could make a long list of serious authors who freely treat power as moving energy. I namrd Ktaus, Ridenour, Purcell, and Walter Maxwell.

Terman was another world-class expert who was unafraid of the word "power". On page 76 of his 1955 edition he wrote:
"Alternatively, a load impedance may be matched to a source of power in such a way as to make the power delivered to the load a maximum (The power delivered to the load under these conditions is termed the available power of the power source). This is accomplished by making the load impedance the conjugate of the generator impedance as defined by Thevenin`s theorem. That is, the load impedance must have the same magnitude as the generator impedance, but the phase angle of the load is the negative of the phase angle of the generator impedance."

I have not yet seen a copy of "Reflections", but would bet that W2DU says the same thing, perhaps in fewer and shorter words.

Best regards, Richard Harrison, KB5WZI

> original posting and the follow-ons for details.

But in your "proof", you superposed powers which is a no-no.
When 111.1mW interfers with 87.78mW, the result is not
(111.1-87.78). Since the associated E-fields are 180
degrees out of phase, the power equation must take the
interference into account.

Pref1 = 111.1mW + 87.78mW - 2* sqrt(111.1*87.78)

Pref1 = 111.1mW + 87.78mW - 197.5mW = 1.38mW

You subtract 87.78 from 111.1 and get 23.32. That value is
almost 17 times too high. All your math after that is invalid.
All except 1.38mW of reflections are canceled by that first
internal reflection. Your value of 23.32 is simply wrong.

RF engineers usually convert to voltage, perform the superposition,
and then calculate the total power. One doesn't have that luxury
when dealing with light so the power (irradiance) equations must
be used to obtain the correct results.

You are technically correct but it doesn't matter. The Sun
will rise tomorrow even if the Sun is fixed in space. I'll
even bolster your argument. RF energy moves at the speed
of light in the transmission line. The power meter is
standing still compared to the transmission line. If the
power meter were moving with the energy at the speed of
light, it wouldn't work at all. Does that help? :-)

The difference between teaching reading and writing and teaching arithmetic is that practical uses for reading and writing are immediately apparent to children. Whereas teachers of arithmetic, and then maths, fail to show children the many interesting and practical uses of the subject.

It's lack of imagination on the part of teachers - and laziness. They have no interest in the subject themselves. They are themselves victims of poor teaching and of the system which selects them to be teachers.

In the UK it can be traced back to ignorance on the part of Ministers of Education.

It is a great pity children are not given the opportunity to appreciate the beauty in Mathematics. In England, first year engineering university students have to spend the first 6 months being taught what they should have learned at the age of 14. Including how to read and write.

Just prior to a General Election (of Members of Parliament) in the UK I once asked a prospective MP what seven nines were. He didn't know! Yet there was the possibility he could end up as the Chancellor of the Exchequer or even as a Minister of Education.

As the meeting was being held in a public house the prospective MP changed the subject and bought me a pint of beer. Presumably in a futile attempt at bribery for a vote.

Eventually he lost his deposit (of £500) for failing to collect the necessary small minimum number of votes.

Hi Greg,

Feed lines that are terminated in balanced loads are self isolating.
The balance of the load is with respect to earth and is discussed
under the heading of Common Modality. So your problems are load
defined, not line defined. Naturally there is a continuum of linkage
between lines even in this best of all possible worlds. That
continuum spans from considerable-to-miniscule and it is, as you have
guessed, dependant upon spacing.

What constitutes considerable may be miniscule for another and I will
leave that determination up to you, as you have offered no limits nor
quantitative concerns. If you need a rule of thumb, keep all lines at
least 10 times their own pair-spacing apart. That is, if a twin lead
has 1 inch spacing between the conductors, keep that twin lead 10
inches from a similar feedline.

There are no doubt authoritative reports to offer a justification for
this rule, or any other offered. I would expect this would come from
Laport's work (which several correspondents here have copies of).

Source record: 72419

Larry,
Is it a 'valid' antenna? Ah, yes, with several 'buts' that
'add to' / 'subtract from' that 'validity'. The 'biggy' questions
are what length and what frequency of use? Those will determine
the input impedance of the thing, and who says that a 9:1 is
going to be the 'right' impedance transormation ratio? That
9:1 thingy is basically taking the place of a tuner, which would
make the thing a much more 'valid' multiband antenna, but not
necessarily a very broadbanded one.
So while there is some validity, I don't think I'd say it was
totally valid, broadbanded, or multibanded. Not bad advertising
though...
'Doc

> use these measured values to obtain my complex impedance at the input
> of the coax cable?

I went through this exercise about 15 years ago using my MFJ-949E.
I assumed linearity for the capacitor setting numbers on the front
panel, i.e. setting 10 = 208 uf. I don't remember what I assumed
for the minimum capacitance zero setting, maybe 10%?. Using a dummy
load and setting the caps near half scale, I then calculated the
different values of inductance for the various switch settings.

For instance, with C1 set to 3.1, C2 set to 3.2, a match was
achieved on 3.5 MHz with the coil set at J. A match was
achieved on 4.0 MHz with the coil set at I. I calculated
52uH for position J and 40 uH for position I.

I wrote a BASIC program that took the switch settings as inputs
and output the estimated impedance looking into the feedline.
I don't know how accurate it was, but it gave me a useful
ballpark value. Ballpark values are often good enough to
indicate what needs to be done next. Shortly after the above
exercise, I bought an MFJ antenna analyzer.

What I found to be a more useful technique is to adjust the length
of the feedline until a purely resistive value is achieved. That
happens at the current minimum points on the SWR circle. An MFJ
antenna analyzer will read that resistive value. Knowing that
resistive value, the Z0 and loss characteristics of the feedline,
and the length of the feedline allows a fairly accurate calculation
of the antenna feedpoint impedance which, at my QTH, agrees closely
with the feedpoint impedance predicted by EZNEC.

Please define "transfer" in this context. The IEEE Dictionary
defines "transfer capability - the capacity and ability of a
transmission line to allow for the reliable MOVEMENT OF ELECTRIC
POWER from an area of supply to an area of need." Emphasis mine.

> But power is not the thing which is being transferred from one place
> to another.

Jim, we can use your logic to solve most of the racial problems
in the USA. Black Americans are not black. White Americans are
not white. These statements can be proven beyond any doubt by
using a light spectrometer.

Therefore, since there are no black people and no white people,
there can exist no clash between black culture and white culture.
All racial problems are therefore declared solved. Next problem?

> 73,
> Greg, N6GK

Hi Greg:

I have just run a free space NEC 2 model of a pair of horizontally positioned 6" wide, 600 ohm, transmission lines, vertically separated by 12". The model was run from 29 to 31 MHz. On 30 MHz , with both lines terminated in 600 ohms the isolation was about 39 dB. With both lines terminated in 6,000 ohms the isolation improved to 66 dB. The actual range of impedances will be much higher, and complex, but it does give an idea of the order of magnitude of the isolation. The calculation is based on the ratio of the peak currents observed.

Hope this helps,

73,

Frank (VE6CB)

I'm looking for an antenna connector with the following idea:

I want to mount a spare 2m/440 mobile antenna on my race bike and use my FT-51R ht on my belt with the deluxe remote mic on the handlebars.

Problem is that if I wreck, the radio will want to stay on my belt but the coax going to the antenna won't! The mic connector will pull out but the antenna connector (BNC) will stay until something breaks. If I wreck, I may need my HT to call for assistance (it's happened once before) I need an inepensive 50 ohm pair of connectors that will slide apart when pulled. Kinda like a push on F fitting but for 50 ohm RG-58 cable.

The only ones I've thought of are the F fitting or an RCA connection. Anybody know the impedance of an RCA plug?

Are there push on BNC or 259 connectors? Cost matters.

I suggest filing the bumps off a BNC female. Without them, the connector halves should fit snugly enough to stay together unless you tug on it. You could use a little tape, a weak rubber band, or something similar to hold it together a little more firmly while riding but which would break away fairly easily.

If you try to use an RCA plug, the connections to it -- where you have to split to coax conductors apart -- will cause a much greater impedance bump than the connector itself. Since your communications seem to be short range, you should be able to get by with a pretty bad impedance bump, though. It would probably have the least effect if it's close to the rig rather than at the antenna end of the coax.

Jim, there are more references on my side than on yours.
Your definitions are esoteric to say the least. My
definitions are mainstream IEEE and agree with many
authors of RF books and power industry standards.

"There is no before and after!" (a quote from one of
your emails to me). Would you mind proving that assertion?

Proving that "Power in the reflected wave" is common
usage in RF engineering. You are not going to get the
human race to stop using the word, "sunrise", no
matter what you say or do.

BS! Please don't confuse my ability to act as devil's advocate
with what are my basic concepts. I have told you multiple times
before over any number of years that I agree with you that power
is energy passing a point or plane in a unit of time. That can
be easily proven to be true with a little Google research. I'm
old-fashioned enough to believe that joules/sec needs a reference
measuring point or plane. That's what I was taught in the 50's and
that's the concept that I still carry around in my head.

What I have said lately is that any number of knowledgeable
engineers and authors have an expanded definition of power.

Now you're vehemently arguing about whether you argued or not.

> What I have said lately is that any number of knowledgeable
> engineers and authors have an expanded definition of power.

That was never in dispute. You argued that power propagates and
reflects, and I explained that it doesn't. Now you're behaving like a
child.

Interesting that the same things have very different meanings.

In my current business 7 nines would mean roughly 3.16 seconds. Can you
tell me why?

the square root of seven nines is 3162.27...

if the figure above were microseconds would be ~3.162 seconds.

Why not just run one pair. Then split off at the end with the antennas.
The signal will take the path of least resistance, so the most likely
antenna for the job will be chosen automatically. The ones with high Z will
resist. Resistance is not futile.

My 2¢ (that "¢" key was tough to find)

Hello,
I'm thinking about suspending approximately 100 feet of 9913 coax on a cable to run it out to my new antenna site. I will be using an ameritron rcs8vl remote antenna switch going to two dipoles and three verticals. What I'm looking for from the group would be an electrically / RF safe method of doing this. I have considered going underground for the run, but would have to go under a patio and over our septic system. Thanks for any ideas.

Jim, you know that isn't true. After you reviewed my article,
I changed every occurence of "reflected power" to "reflected
energy" just to satisfy you. You have never been able to
back up your assertions about what I have said with any
quotes of mine. Wonder why?

So once again, I challenge you to produce a quote where I
said power propagates and reflects. I have always said that
energy propagates and reflects and power is the measurement
of that energy flowing past a point.

Thanks for the $.02 worth...it would be a good idea for me, but I will have several antennas (of various types - dipoles, vee beams, etc.) capable of being used for the same band, but at different angles from each other. I hate to "share" my antennas and mess up the patterns I want to use. I thought about switching way out back, but kind of hard to do A-B testing when I have a 500 foot run to switch the antennas and get back to the shack! I'm too old for that!

Thanks Frank for running the program and for the results. They give me a good confirmation of what Riachard Clark showed me, I need to get more space between these feeds than I was planning on. If I had 3 feeds, I guess I ought to have a cross arm on my wood/PVC poles coming in and spread the feeds by about two feet to minimize the interaction down to a miniscule amount. I really do want to feed the antennas separately. Gee, I wonder what W6AM used to do with his 10 or 12 rhombics fed with open wire all coming into his home...

Source record: 72299

Wow, then if I had 6" spacing, it would have to be 5 feet from the nearest other feed line! With the three lines I want to bring in, that is a cross pole of 10 feet! Wow...I better consider using my old 450 ohm window ladder line with about 1.x inch spacing so I can get down to a reasonable spread!

This is really opening my eyes up to the logistics of running this type of feedline...low loss, but definitely more expense, bother, etc. than running a bunch of coax lines! It almost makes me want to put up resonant antennas (like parallel dipoles, fed with a balun and coax...so much easier!). I'm going to have to think this through some more.

Thanks for the input,

Greg, N6GK

Jim, here's a posting from last year that proves your assertion
to be false. I agreed with you last year that power doesn't
flow and isn't reflected. I agreed with you that it is energy
that flows and is reflected. I agreed with you that power is
measured at a point. Seems an apology is in order.

But energy does flow and move and is something that can be reflected.
You can easily see the energy packets using a TDR. Without energy,
those pulses wouldn't exist. The energy is obviously in the pulse,
where the voltage and current are.

And joules of energy flowing past a point is joules/sec, i.e. power,
by IEEE definition.

Sure. I know exactly what the problem is. In certain situations
(especially when using the recent Dell issue wireless G chipsets in
conjunction with the Netgear access points, an unhealthy high amount of
static impedance buildup occurs in the surrounding atmosphere,
particularly in areas of low and medium elevation (in mountainous high
elevation regions this isn't nearly the case) as I am sure Dell Support
has probably already explained. There a few ways to get around this. Do a
query of all wireless devices, microwave ovens, RC devices and pleasure
clubs (planes, and cars) and garage door openers. You will then need to
place such devices under the inspection of a valid, certified operator of
a high thermal stability micropower voltage reference meter. This sounds
like a great deal of effort and expense but any typical radio shack
employee could probably offer the service remotely for a fee of around 10
bucks or less (or at the very least turn you in the direction of some
inexpensive alternative.

You can try to use a static defusing device by placing large pieces of
Styrofoam on top, beside, and underneath your wireless access devices.
You might also want so smear a small amount of viscous material upon the
antenna and external interfaces of your laptop and access point. This
often fixes the problem as well.

I worked in HF radio stations briefly a long time ago, and the
practice there was, IIRC, two wire lines of 3mm HDC with 200mm spacing
so they were around 600 ohms 'ish. There were also some 4 wire lines
with similar spacing (in a box config). These lines were strung out on
pole routes with separation about double the wire spacing. I can't
remember now if there were periodic polarity reversals. These were at
rx only or tx only facilities, so receiver de-sense was not an issue.
Do you need full duplex?

Clearly, the closer the lines the higher crosstalk (coupling from one
line to another), and presumably, twisted lines will have lower
crosstalk (think about the cat5 etc data cables).

Don't forget, that the antennas at the far end are coupled, and
achieving crosstalk of -100dB might not materially improve the
solution!

A pole route carrying a number of lines is a pretty serious project
(installation and maintenance). I would also look around at remote
switching solutions or multiband antennas to see if you can minimise
the number of lines you need to string.

Owen

Take a look at SMB or SMC coax connectors. One of those, IIRC, is a push-on
style, and should uncouple before damaging the coax line.

All,

I've been listening to this guy on 80/40m with his 60m high antenna, he's a huge signal with me and indeed crashed over the top of the pileups for the PY's on 40m the other eveningm now I see he is selling them.

Might be worth a look if you have a small garden as it would appear it works fine from this type of QTH.

yep, works fine, lasts a long time, much easier to construct. the only down side is that some people don't like to look at it.

Hi

I'm looking for the software "Terrain Analysis" from K6STI or equivalent.

I do not find any links on the web to get it !

Is it still actual ? Is there equivalent (or better) software ?

Thanks a lot

Best regards

Would that be HF Terrain Assessment? It computes the effects of local terrain on the radiation pattern of antennas. The software was developed by N6BV, and is given free with purchase of the ARRL Antenna Book. See www.arrl.org

Greg Knapp wrote:
"I need to feed many different antennas with open wire line and need to run the feedline from each about 200 feet from the back pasture to the shack."

This is similar to the problem facing commercial shortwave stations. They usually have more distance and numbers of antennas and transmitters to serve several target areas simultaneously.

The preferred solution is a feedline for each antenna. These separate lines converge on the switching location near the plant. Each transmitter is equipped with its own feedline too. These converge on the switching location too.

In the "crossbar" switching arrangement, any transmitter may be connected to any antenna. Very flexible and it works well.

When separate lines are too extravagant, a single line is switched at both ends between some transmitters and some antennas. You need at least as many lines as you have transmitters if all are going to operate at once and not in parallel.

Most commercial stations have multiband radios but use narrowband antenna systems. This requires many more antennas than transmitters to serve many different targets in various bands required on the various paths around the clock.

If you had only one direction or sense to serve, a single rhombic connected by a single line to the transmitter might do a compromised job. The rhombic will take a load at almost any frequency, but its pattern changes with frequency so its coverage of a target won`t be ideal at most frequencies.

If you don`t want to walk 200 feet to switch antennas, use relays controlled from your shack. That`s what professionals do.

Best regards, Richard Harrison, KB5WZI

No Problem Greg, glad to help. Just for interest I ran the program at different spacings: at 6" the isolation is 27 dB, and at 2 ft 48 dB. Both these measurements with 600 ohm terminations.

Balanced transmission lines radiate very little energy, but worst case occurs at the higher frequency. For example the maximum radiated RF from a terminated 600 ohm transmission line, at 30 MHz, is about -28 dBi.

I have seen pictures of W6AM's transmission lines, but can no longer find them on the web. His antenna farm, as I understand, was purchased from a commercial HF station. Interesting little article on W6AM in http://www.mvarc.com/images/mvarcJULY05pp9.PDF

Complicated. Do as phone and cable companies do. Use a messenger cable to uniformly support the coax along its length. No cable strain or connector separation. Take care waterproofing all joints.

> power?

I think I understand Jim's point that power is measured
relative to a stationary point or plane. The Bird wattmeter
is stationary in the transmission line and measures the
average energy/time flowing through it. Average power is
averaged over at least one complete cycle. It is hard to
visualize an average power meter measurement while the meter
is moving with the wave - admittedly an esoteric point and
not likely to have any effect on common usage.

Consider that it is the instantaneous value of voltage and
current that is reflected (actually the instantaneous E-field
and H-field). The RMS value of voltage and current is not
what is actually reflected in reality. But again, shortcuts
and common usage rule the day.

I'm sure a lot of antennas work well when they're 60m high -- that's
about 195 feet off the ground, if my math is correct. Just the thing
for that "small garden."

Source record: 72319

I really can't answer how important the coupling factor is because I have never dealt with this factor before.
I assume the only down side of too much coupling is that some small amount of RF would then be coupled to the wrong antenna and radiated in some pattern that is not necessarily desirable. So, as I understand it (I sure could be wrong), if I was running a 1000 watts out, with coupling at -30 db, 1 watt would be coupled to the parallel line which would then be radiated by the wrong antenna--which, if true, certainly doesn't seem significant. I am not sure what is a significant level (i.e., significant distortion of net radiation pattern) in dealing with two simultanteously feed antennas, but I would think that if it is a ratio of the transmitted power, then 1000 vs 1 watt would seem to cause very minor distortion and would seem to be acceptable. If my reasoning is OK, then I would think spacing of feedlines would not need be too great, even if 5-inch spaced 600 ohm was used in place of 1.x inch spaced 450 ohm line.
Any insight would be appreciated.
73,
Greg, N6GK

>horizontally one foot apart from each other? How much is enough separation?
>What other precautions do I need? Need they be twisted if they are not near
>anything other than the other feed lines?

I probably have more questions than answers.

1. Are the antennas to be operated independently? Is this a duplex or
diversity system?

2. Will the unused lines be terminated in the shack?

3. Are these multiband antennas with tuned feeders or could they just
as easily be coax-fed?

4. What do you consider to be detrimental interaction?

As others have suggested, there will be coupling between the antennas,
so feedline-to-feedline isolation will not necessarily be a figure of
merit.

If you consider the impedance change of a single pair of wires
operated over ground as a proxy for interaction, then with separation
by 3 or 4 times the wire spacing, you are probably okay for all but
the most critical situations.

One test would be to excite one line and measure the power in an
adjacent line, remembering that some (a lot?) of the coupling will be
antenna-to-antenna and will also be frequency dependent.

Hi Greg,

Frank has been carrying a lot of water for you in this regard. I would point out (and he has stated as much) that his numbers are for a load of 600 Ohms. Now, any mismatch will not have any impact on the coupling, but the load's balance to earth will and Frank has done no study of induced Common Mode currents. Given that there is a world of possible imbalances possible, it is hard to know where to go from there.

There is also a world of probable imbalances too. The antennas you are feeding are far more likely the source of the problem of coupling between lines than are the lines' proximity. However, proximity only magnifies the problem. Still and all, even the worst imbalance is unlikely to pose significant issues. It might be problematic for a VOA feed of 500KW with leakage of their European service into their African service, but you are not in that class (and they probably now how to keep their antennas balanced too).

Jim Kelley wrote:
"---power does not flow or move, nor is it something that can be reflected."

From the Random House American College Dictionary:
Power is the ability to do or act. It is the time rate of transferring or transforming energy. It is work done or energy transferred per unit of time.

The power to do or act can be moved from one location to another. A power house is an electrical generating station where some other form of energy is converted to electricity which is very flexible in application.

From the power house, the power (ability to do or act) is transported by power transmission lines to the places it is used.

Since the wavelength at 60 Hz is 5 million meters, (5000 km), power transmission lines aren`t long enough to produce standing waves which are caused by reflections.

Radio-frequency transmission lines are often long enough to show the effects of reflections and the standing waves produced by those reflections.

Power flows in r-f lines and it is reflected at impedance discontinuities accordimg to the most knowledgeable experts. F.E. Terman is my favorite.

> power?
>
> Walt, W2DU

I hope I haven't given the impression that I would be unfamiliar with
that relationship. I used it in my work practically every day of my
life for many years.

Here's my best answer to such a question. According to the physics that
I've studied, physicists seem to be laboring under the impression that
it is the electric and magnetic fields which actually propagate and
interact with matter. That interaction can result in, among other
things, reflection. The E&H fields manifest themselves within matter as
voltages and currents, respectively. Although it is the fields which
reflect, it is the resulting voltages and currents that we can most
readily measure. From a practical everyday standpoint this distinction
makes little or no difference. It is only when we start to describe
physical processes such as energy flow that it may become necessary to
consider the distinction.

And yes, if you take a calculator or slide rule and multiply voltage and
current, and make certain assumptions, you can find the rate at which

energy is probably being transferred from one place to some other place. But some folks have argued descriptions of physical phenomena derived from an assumption that the number displayed on the calculator physically propagates through a transmission line, physically reflects off the ends of the transmission line or other discontinuities, and physically interferes with itself or other numbers like it. So that there is no further mistaking my position, I dispute the validity of these descriptions of the behavior of physical phenomena, and some of the predictions based upon them. I do not dispute P=V*I, but thanks for asking.

The wave which propagates along a transmission line can produce energy at a rate proportional to E x H, but it is not E x H which propagates along the transmission line. E propagates in one plane, and H propagates in a plane a right angles to E. When we know the characteristics of E and H (or V and I) individually, we can predict what will occur when either encounters a discontinuity. But when we multiply to two together, the resulting magnitude no longer possesses the properties of either of the multiplicands, and so no accurate predictions about interactions with discontinuities can truly be derived without making assumptions. And as we've seen, given a nebulous laundry list of assumptions, some inaccurate predictions can be derived.

Your 'Transformer' diagrams come as close as any I've seen to describing how things behave in an coaxial impedance matching arrangement. I hope you include them in your 3rd Edition. I have, by the way, found similar but less detailed drawings of thin film interfaces in two different physics textbooks. I think the key to understanding them is the superposition of multiple reflections.

Whatever floats your boat, Richard. If you need to think of power as an 'ability' that flows through an electrical pipe, then I think you should think of it that way.

Hi Jim,

Such coverage as you describe, in physics textbooks, are rudimentary
discussions suitable for introductory purposes. They are not the
end-all be-all nor final word on the matter. This is born out by
exhausting work being pursued by many in academia and the industry to
"completely cancel" reflections. They would not be so engaged in this
work if a simple, quarterwave, thin layer optic performed this
complete cancellation already. The fact of the matter is that by the
mechanics so described in the text books, they guarantee no totality
of cancellation. True, they offer a close hit, but this is not proof
of totality. Close is good enough for nuclear hand grenades too.

When the energy available in the first medium, at the second
interface, cannot possibly reflect enough of it to the first
interface; then no amount of superposition of ALL reflections (and
this presumes that the second interface is fully reflecting for these
succeeding multiples, an absurd notion in its own right) can exceed
that available energy.

Yes, this has all been said before, you've found it interesting but
not compelling; and yet no one here has offered any way to boost the
energy to completely cancel the reflection from the first interface.

Under the circumstances already described, those reflection products
(after assuming ALL the multiple reflections have been ushered out
from behind the first interface to destructively interfere) contain:
1800 TIMES MORE POWER THAN THE SUN!
which has been humorously relegated to zero. :-)

Flowing, dribbling, puddling, or simply expressed in terms of candelas
per square foot per fortnight, it all leads to the same conclusion:
the cancellation is not total. Hence the subject line of
The Extreme Failure of Poor Concepts
in Discussing Thin Layer Reflections

Hi Richard.

The example you provided earlier is not any result of exhaustive research. It is not even an accurate thumbnail sketch of the phenomenon at the level of "rudimentary physics books". So I disagree with your assessment. (Perhaps you should consider having a look at the text you're characterizing first before you presume to characterize it.)

But if by all that you mean to say that it's not possible to make a perfect anything, then I think that ordinarily goes without saying. So yes, you're right. There is no such thing as a lossless medium.
But it is a rather simple matter to get a reasonably good match using this technique. I think you can assume that's about the degree of accuracy we're using for most of our discussions.

73, AC6XG

PS I like your power flow analogy. :-)

3867. Aluminum siding & proximity to loop antenna

Hi Jim,

This is what I mean by no argument being put forth to dispute what has
been offered. In fact every computation offered flows from the math
offered by ANY academic text. I even name the math used, and then use
it. In fact, I have lead the way by offering every cogent formula
needed to discuss this matter.

I see no dispute in the assignment of indices of reflection. I see no
dispute in the computation of reflections. I see no dispute in the
balance of energy at each interface. And I am speaking of
quantitative results, not presumptions. The chain of causality is not
very long, it exhibits very obvious contradictions to the notion of
"totality," and the practical example is hardly from the sphere of the
wildly imaginative. The example is further exhibited as a practical
problem of current research.

>So I disagree with your assessment.

OK, so you disagree, but that is not an argument, it is simply a
statement of prejudice.

> (Perhaps you should consider having a look at the text
>you're characterizing first before you presume to characterize it.)

and this is a characterization of its own.

>But if by all that you mean to say that it's not possible to make a
>perfect anything, then I think that ordinarily goes without saying.

What I mean has been clearly stated. Adding qualifiers on my behalf
goes outside of the discussion.

>So yes, you're right.

I state nowhere that "perfect" is expected, nor do I impose that as a
condition. Can we leave these speculations outside of the discussion?

>There is no such thing as a lossless medium.

This is a non-sequitur injected for no apparent reason. Why so?

>But it is a rather simple matter to get a reasonably good match using
>this technique.

You've gone to great lengths to extrapolate and postulate what I've said, and yet fail to commend me for having said just this any number of times. Why so?

>I think you can assume that's about the degree of
>accuracy we're using for most of our discussions.

For "Total cancellation?" If you accept that, you've spent four years arguing for... what have you been arguing about? Have you allowed this slack you accept in our behalf for your own positions? However, I am used to the "debate" that proceeds along these lines where "Totality" has been proven, accepted and it leads to nonsensical theories like waves reflecting waves.

Reminds me of a point made by Tom Whitaker, a two-handed blackboard scribe and celebrated E.E. Prof I had over 1/2 century ago. Tom wrote with one hand and erased with the other so he would have a clear space to write more.To drive home his definition of current, Tom spat on a piece of chalk and chunked it with vigor the length of the auditorium where it bounced harmlessly from the rear wall. What an arm! Some ball club sgould have signed him.

Tom said: "That spit was charged and you`ve just seen an electric current!

Your D-cell holds much charge and rolling the cell puts charge in motion, So, yes, power has flowed because you transferred the ability to do work from one site to another.

You should consider lightning, if it's common in your area.
If you take a strike at the antennas, the potential at the shack
end of that elevated coax will be huge. I would have some way
to disconnect and ground outside, if you were to do that.
In general, elevated coax is not a great idea, although there are
no "rf" problems in doing so.

Hi John, Since it is not recommended to mount a loop antenna or any other kind, near aluminum siding, I doubt many here have done so. May not get comments about doing the undesirable.
On the other hand, a 160m full wave loop will be so large in comparison to the small section that is in proximity to the aluminum siding, you may not be able to tell much difference whether the siding is there or not. Same thing with a full wave 80m loop. I would go for it.

I've seen dispute of your numbers. Cecil had them right. Cecil is very
good at getting the numbers right. I even agree with the solutions to
his irradiance equations. He and I disagree only on certain details of
the physical mechanism (though he seems to want to disagree with just
about anything I have to say).

Start with a presumption that it is not a non sequitur and see where
that leads. I've reassembled my original statement above for your review.

>>I think you can assume that's about the degree of
>>accuracy we're using for most of our discussions.
>
>
> For "Total cancellation?" If you accept that, you've spent four
> years arguing for... what have you been arguing about? Have you
> allowed this slack you accept in our behalf for your own positions?

The relevance of the "non sequitur" stated above thereby makes itself
apparent. There are several reasons why it is difficult to achieve
total cancellation of reflected light at an optical surface. First -
the obvious one. A quarter wave layer is only a quarter wavelength
thick at one wavelength. Second - dielectric films can be lossy. Third

- anti-reflection is only 100% effective at normal incidence. Fourth - it's next to impossible to make a film that has a refractive index which is the perfect geometric mean of the indices of the media at its boundaries.

A thorough treatment of all the reflections at both boundaries, whereby all in-phase reflections in a given direction are summed, provides that absent the imperfections described above, total cancellation is indeed a fact. Another fact is that it's much easier to accomplish in a transmission line with monochromatic RF at HF.

> However, I am used to the "debate" that proceeds along these lines
> where "Totality" has been proven, accepted and it leads to nonsensical
> theories like waves reflecting waves.

If I were to characterize most of the discussion I've had here, I would say most of it has been spent addressing misunderstandings related to the fundamental behavior of nature.

Thanks for your comments, but a full-wave loop antenna is much larger than I had in mind. The ARRL Antenna Book contains a write-up about a loop antenna that is 100 feet in total length. It is built in the shape of an octagon with 3/4" copper pipe, and contains a capacitor in series with the side directly opposite the fed side. The loop is mounted with its plane vertical, and the fed side perhaps a foot off the ground so the lawn mower can go under it. The capacitor has to be tuned remotely and has to have a rather large voltage rating. The article implies the antenna has a 2:1 tuning range.

An alternative one-band antenna is the DLM antenna and might be worth trying. See
http://www.uri.edu/news/vincent/boxboro_files/frame.htm

If you think that's what I said, you are suffering from delusions.
All of my power components exist at a stationary point or plane.
The two components associated with wave cancellation exist at the match
point. "Reflected power" is the reflected energy flow per unit time
measured at a point by a stationary directional wattmeter. "Forward
power" is the forward energy flow per unit time measured at a point
by a stationary directional wattmeter.

Power components do not interfere. It is the E-fields and H-fields
that do the interferring. However, given the interference of two
coherent waves traveling in the same direction, the following
power equation is valid.

Ptotal = P1 + P2 + 2*sqrt(P1*P2)cos(phi)

where phi is the phase angle between the two E-fields. The last
term in that equation is well known as the "interference term".
If cos(phi) is negative, the interference is destructive. If
cos(phi) is positive, the interference is constructive. If an
additional source of energy is not present at the interference
point, the destructive interference must equal the constructive
interference to satisfy the conservation of energy principle.

Like I said before, the only disagreement that we have left is
whether dt is zero or infinitessimally small. Your straw men
are just straw men designed to mislead the uninitiated.

Note that Richard Clark is NOT using the above power equation
and is instead trying to superpose powers which is an invalid
practice. That's why he's calculating the wrong values.

John,
For what it's worth (not much), I used to run a 1/2 wave dipole over a metal roof. It worked. The input impedance was reasonable, certainly not the best, but reasonable. Your loop wuold show some directionality, I would think, but that may/may not be 'bad', and the input impedance ought to be adjustable with the capacitor, sort of, maybe. Also ran a full wave 80 meter loop around a building with aluminum siding. Had pretty fair clearance all around, so didn't really affect things much (I'm sure it did, but it worked so who cared?). Give it a shot, see what happens, then tell us!
'Doc

3876. Re: How Handle Multiple Open Wire Lines?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-03 23:56:25 UTC
From: greg knapp 5 <gknapp@freshrain.org>
Message-ID: <tLOdnezS58E0xGzfRVn-uw@speakeasy.net>
Source record: 72242

As an alternative to running the feelines of my proposed multiple antennas (dipoles, vee beam, etc.) in parallel 250 feet from the back pasture, I've come up with an idea for remotely switching the feedlines. Here's the idea for handling multiple open wire lines...switch them remotely using only the center of the coax fittings on a remote coax antenna switch (the type that switch 4, 6, or 8 coax antennas).
This might be accomplished at least three ways:
1) just hook one side of all the feedlines together and switch the other one by plugging them (using banana plugs or similar) into the center conductor of the coax fittings
2) have two coax switches, so that both sides of the feedlines are kept separate and switched by throwing two coax switches in synchronization.
Which of these would work best, or neither? Would the impedence bump cause any significant problem? Has someone actually tried this? What about proximity between the feedlines gathered around the switches...would that cause significant problems at the legal limit (I notice Cecil's switch design has them pretty close to each other...but not this close)?
3) give up and go back to parallel lines until they reach the shack and switch them with banana plugs.
One kind person responded privately with a picture of W6AM's home showing the independent openwire feed lines going into the house about 8 different places spaced about 2.5 feet apart, obviously to either dedicated tuners/rigs or some horrendous switching network that was knife thrown. I really don't want to do that, if I can avoid it.
This all is getting so complex, to presere my sanity and pocket book I might just be forced to go back to resonant antennas on all bands so I can use coax without undo loss! Hi!
73,
Greg, N6GK

Right. That's simply because P is proportional to E^2.

> The last
> term in that equation is well known as the "interference term".

Basically, yes. Two times the product of the two fields is the
interference term. The product of two things which don't interfere is
probably inappropriately referred to as an interference term.

> If cos(phi) is negative, the interference is destructive. If
> cos(phi) is positive, the interference is constructive. If an
> additional source of energy is not present at the interference

> interference to satisfy the conservation of energy principle.

....and by virtue of the fact that 2*sqrt(P1*P2) = 2*sqrt(P1*P2). ;-)

> Like I said before, the only disagreement that we have left is
> whether dt is zero or infinitessimally small.

As I recall, my disagreement with you was about your claim that
"interference causes energy to reverse direction and go the other way".
That's what it's always been about, Cecil.

Do you still insist that's what happens? If not, then we're in
agreement - unless you disagree, of course.

> Your straw men
> are just straw men designed to mislead the uninitiated.

Actually the "straw men" seem to have brought you around substantially
to the correct point of view. And I really don't think anyone who's
been paying attention is misled about you, Cecil. :-)

There you go. Run a piece of Heliax out there and use one of your
coax relays as it was intended.

Even at SWR = 3:1 @ 28 MHz, 200' of 1/2" Heliax will lose only about a
dB. Use 7/8" line and you could stand 5:1 for less than a dB.

Hi Jim,

Well, being blunt offers no more argument than previous statements of
prejudice. And the point of the matter is I've observed no one here
offer any math in advance of my presentation. If this is
overestimating any significance, it certainly puts everything else in
the shade.

And yet and all, you have nothing at your fingertips:

A dispute over indices of refraction? Nada.

A dispute over reflection? Nada.

A dispute over balanced energy equations? Nada.

All rather first principles and central to the discussion. It takes
very little effort to unscramble a half page of text if I've so messed
it up; but I am content to see you are aligned with Cecil's argument
and to watch where that leads. :-)

It could lead to another fruitful 4 years of

But energy does flow and move and is something that can be reflected.
****

In that posting, I am agreeing with you but your delusions make
you assert to this very day that I was arguing with you.

>> Power components do not interfere.
>
> Glad you finally agree.

I have never said otherwise. I often identify the wave component
by the power figure, but it is *only a name* used to identify
an EM wave. When I say, "The 50 watt wave interferes with the
25 watt wave", I'm not saying that 50 watts interferes with
25 watts. It's the *waves* that interfere, not the watts!
Why is that so hard for you to comprehend?

>> Ptotal = P1 + P2 + 2*sqrt(P1*P2)cos(phi)
>> where phi is the phase angle between the two E-fields.
>
> Right. That's simply because P is proportional to E^2.

I'm glad you finally agree after arguing against it for years.
(See, two can play your junevile game.)

>> The last
>> term in that equation is well known as the "interference term".
>
> Basically, yes. Two times the product of the two fields is the
> interference term.

The interference is in the units of power, e.g. joules/sec.
It is two times the square root of the product of the two powers
associated with the two interferring waves. It is the result

of superposition of two coherent EM waves. As I said before,
it is the waves that interfere, NOT the powers.

>The product of two things which don't interfere is
> probably inappropriately referred to as an interference term.

Your argument is with Hecht and other scientists, physicists,
and engineers who use that convention, not just with me. You
would have made a good lawyer since you seem to object to
virtually everything. :-)

>> Like I said before, the only disagreement that we have left is
>> whether dt is zero or infinitessimally small.
>
> As I recall, my disagreement with you was about your claim that
> "interference causes energy to reverse direction and go the other way".
> That's what it's always been about, Cecil.

Destructive interference in one direction in a transmission line
results in constructive interference in the opposite direction.
Anything else would violate the conservation of energy principle.
Our argument is whether destructive interference has time to happen,
i.e. how many calculus dt's can dance on the head of a pin. :-)

Whether interference can cause energy to reverse direction or not
depends upon whether dt equals zero as you imply, or whether dt equals
an infinitessimally small amount of time as I say. That's what it's
always been about, Jim.

> Do you still insist that's what happens? If not, then we're in
> agreement - unless you disagree, of course.

If dt is an infinitessimally small amount of time, then that is
exactly what happens. If dt equals zero, then it doesn't have
time to happen. Your argument is that it doesn't have time to
happen because "there is no before and after". (a quote from your
email). I say there is a before, now, and after divided into
infinitessimally small dt's of time and when added together,
actually perform the function of representing the flow of time.
So are you going to assert that time also doesn't flow?

From your description the antenna is a 100-foot-perimeter magloop for
160 and 80 meters. With a 3/4" diameter conductor it will do fine.

Provided it is not facing and very near to the side of the house it
should tune up and work OK. Have the plane of the loop at
right-angles to the siding, NOT parallel to it. If you can't manage
this then don't bother erecting it.

I would not like to see the edge of the loop any nearer to the siding
than 1/4 or 1/5 of its diameter. (Apparently it is intended to work
within a few feet of the ground.)

Aluminium is a good conductor, nearly as good as copper. Negligible
loss will be induced in it. Most loss will be in the ground by virtue
of its very low height. The close proximity to ground will also cause
unoticeable detuning.

The presence of the siding will slightly detune the antenna but you
will not notice the difference because there is no way to make a
comparison. But if there is an intermittent contact between the
siding and other walls or metal roof of the house you can expect
trouble. Magloops are VERY sharply tuned!

The radiation pattern may be considerably different from normal. But
again, you will not be aware of it. The broad lobe in one direction in
the plane of the loop may be stronger at the expense of the opposite
direction towards the house.

I have myself run a near-to-ground 160-meter magloop very near to the
brick wall of the house and experienced the detuning which I assume
was due to being adjacent to internal domestic plumbing and house
wiring. The effect disappears when the loop is half its diameter away
from foreign conductors.

The performance of your proposed loop in normal surroundings can be
investigated by easy-to-use program MAGLOOP4 which can be downloaded
from the website below.

I have multiple times, Richard. When a 111.1mW wave interferes with
an 87.78mW wave, the result is *NOT* a 23.32mW wave. It's the waves
that interfere, not the power.

111.1mW - 87.78mW = 23.32mW is superposition of powers and is invalid!

Instead of superposing powers, the equation you need to use is the
power interference equation:

Pref1 = P1 + P2 + 2*sqrt(P1*P2)cos(180)

Pref1 = 111.1mW + 87.78mW + 2*sqrt(111.1*87.78)(-1)

Pref1 = 198.88mW - 197.51mW = 1.37mW

Thus after only one internal reflection cycle, the reflected power,
Pref1, is reduced to 1.37mW, not to 23.32mW as you have asserted.

If you will use a transmission line example and deal with voltages, you
will be able to diagnose your mistake. Voltages interfere, watts don't.
Most RF engineers simply do not understand how to deal with powers
associated with component wave interference.

3891. Re: How Handle Multiple Open Wire Lines?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-04 03:25:43 UTC
From: greg knapp 5 <gknapp@freshrain.org>
Message-ID: <JKKdneAoGI4kF2zfRVn-uA@speakeasy.net>
Source record: 72257

In answer to your questions below, I would expect to only use one antenna at a time, switching between them when wanting to use a different antenna or directivity.

I would expect to use banana plugs to short the unused antennas to ground just outside the shack, hooking up only the one to be used. I don't like the idea of having an ungrounded feedline...lightning/static discharge hurts!

The open wire/coax question is a good one. Some of my antennas will be open wire (vee beam, center fed 80 meter dipole for 80-10 meters), but others, another dipole for 80 at 90 degrees and 150 foot separation is resonant and fed with coax, while I have two verticals fed with coax, plan to experiment with wire LPDAs, etc. So I am trying to think this thing through now, especially in buying a tuner, as I can't afford both a Balanced tuner (ala Palstar BT1500BAL) and an Unbalanced L tuner (TenTec 238B).

I feel like I have gotten a college education on balanced feeds and it's caused me to reevaluate if that is really the easiest way to go. I started out thinking about using just ONE antenna (80 or 160 dipole center fed with 600 ohm line) up about 75 feet on a 45 foot light weight tower and 30 feet of mast above that. I liked the gain on the higher (20-10 meter) bands, but the patterns wouldn't all be in the directions I want given the orientation I have available for the antenna. So I started thinking about TWO such antennas, with the second one on a 40 foot pushup mast. The I thought about adding the Vee Beam I used to have long ago...really worked well on 20-10...definitely a good antenna with the 2 acres I have. And so forth. As most of these antennas would be for multiband use, a balanced tuner would be ideal, but then I had the questions of how to route the feedlines to keep them out of the other antenna fields and away from each other. Having always used coax, this is starting to seem like a nightmare. I almost think the best is to do as one gent suggested, just put in an 80 meter or 160 meter loop, feed it with 450 or 600 ohm, and all it a day.

As I am no longer an avid DXer (used to have stacked beams for 10 through 40), but enjoy chatting on all modes on all bands, with reasonably good signals, I think perhaps at the end of the day maybe the two 80 meter dipoles at right angles (roughly forming an L from a top view) but about 100 feet apart, with one at 75 feet and the other at 40 feet might be the solution, fed with 600 ohm to EITHER a balun-coax-L tuner or direct to a balanced tuner. Good enough is good enough. Of course, I just know I'll throw back up the 300 foot Vee Beam for 20 through 10 at some point, health permitting.

Oh, so many choices and dreams! I think I am going to start small, probably the dipole at 40 feet 350 feet away. That will satisfy until I get the tower refurbished and up in September. The reason I have had so many questions is

because I am trying to foresee what my needs will be a year from now...I
don't want to say, gee, I should have thought of that!

Nope, most misunderstandings are semantic. Most of our arguments
have been because you misunderstood what I was trying to say and
that unfortunate condition continues. You don't seem to possess
the normal human capacity to say, "Sorry, I misunderstood".
(I wonder if God is capable of misunderstanding?)

Hi Fred,

You've missed the point entirely, the equation above already consigns
1.37mW to total darkness. Or any other non-zero result is reduced to
zero for rhetoric's sake (I will skip the love fest of agreement that
did not blossom).

Odd how far this got with everyone presuming that these powers,
energies, or candelas per square foot per fortnight were visible in
the first place (perhaps to some breed of Ubermensch). They happen to
inhabit the deep infra-red.

Classic Katzenjammer. More succinct than the "Who's on first base?"
math.

3898. The Reality Compared to Poor Concepts in Discussing Thin Layer Reflections

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-04 05:47:32 UTC
From: Richard Clark <kb7qhc@comcast.net>
Message-ID: <sl93f15025sjkj29cb32j1q16ve709a9mf@4ax.com>
Source record: 72264

Well, given the tremendous correspondence that attended the other
threads, dare I pause to offer something from the realm of the real?

Yeah, a joke given the classic divergence from topic that inhabited
them. One thing was painfully obvious in such discussion of "seeing"
or rendering reflections "invisible" that inhabited the last
discussion. Here I will offer what is taken for granted in the
optical world, solar cells are largely confined to energies that are
not visible. Very little of the Sun's energy is. This is a natural
conflict between perception and reality - but it is in harmony with
the objections I've observed. ;-)

Returning again to the solar cell, described in text as:

```
1w | 1/4WL |
laser-----air-----|---thin-film---|---Germanium---...
1st medium | 2nd medium | 3rd medium
n = 1.0 n = 2 n = 4.04
```

where the second medium might be Arsenic trisulfide glass or Lanthanum
flint glass.

When you take the intensity times the area for both the reflected and
refracted beams, the total energy flux must equal that in the incident
beam. That equation appears as:
(rï¿½ + (tï¿½ ï¿½ n2ï¿½ ï¿½ cos(theta-t) / n1ï¿½ ï¿½ cos(theta-i))) = 1

It stands to reason that this can be quickly reduced without need to
use transcendentals for an angle of incidence of 0ï¿½ (which results in
a refractive angle of 0ï¿½). All that needs to be known are the
coefficients which for that same angle simplify to
r = 0.667 a value that is the limit of an asymptote;
it is also invested with either a + or - sign depending
upon the polarization (another issue that was discarded
in the original discussion as more unknown than immaterial)
t = 0.667. a value that is the limit of an asymptote;
here, too, there are polarization issues we will discard as
before. All this discarding comes only by virtue of squaring:
rï¿½ = 0.445
tï¿½ = 0.445
I presume that the remainder of the math can be agreed to exhibit:
that part of the energy reflected amounts to 11%
and that part of the energy transmitted amounts to 89%.

The discussion in how the second interface does not have enough incident energy to completely cancel the first interface reflection has been established in earlier threads. What follows is how this correlates to current optical designs to resolve this (industry and academia is not shy in this effort). They, unfortunately, lack the cavalier mentality to simply dismiss their problems as "invisible."

There are several methods of thin film construction, what has been described above, and diffraction on periodic grating. With the work at the Walter Schottky Institute, reflection on bare, highly polished material varies between 11% and 60%. When married to a glass thin film as described above, the variation smooths out to between 6% and 8%(comparable to the example above, but instead using SiGe alloys without regard to quarterwave mechanisms).

When the same researchers employ amorphous silicon on ZnO (again with the mechanics of layering much as described above - still without regard to quarterwave mechanisms), then the average reflection still resides in the region of 10%.

These results are in comparison to the native reflection values of 30% to 50% across 80% of their BW. So, without reliance on this presumption of interference wave mechanics, the practitioners in the art manage to better their performance by five fold - but quite far from absolute.

When we return to study the wave mechanics, we can understand why developers are going for the simpler, diffraction techniques - the wave mechanics are a bust.

Work at the National Renewable Energy Laboratory reveals the purpose of their goal:
"Although highly efficient double and triple layer AR coatings are available, most manufactured crystalline silicon photovoltaics employ simple and inexpensive single layer AR coatings, with relatively poor AR properties."
[AR meaning "Anti-Reflective"]

They are investigating Solar Cells with refractive indices of 3.5. As evidenced in their mission statement, the wave mechanics approach is a bust in comparison to their graded index method (a common technique in fiber optic construction for pretty much the same purpose of controlling energy). They construct the layers by increments of decreasing porosity through a continuous gradient from the index of air (1.0) through to the index of Silicon (3.5). This increases Solar Cell performance by 25% and reflectivity falls to values within 4% to 6%.

Well, two different matching mechanisms employed and they both come to roughly the same results as an answer to the failure of wave mechanics in the single, double, and multiple interference layers (some up to 20 layers). It is not surprising, but let's examine the best that there are to offer, as foretold in the mission statement offered above.

We are returning to the amorphous silicon whose native reflectance runs at 40+%. Researchers have attempted to reduce that through quarterwave thin layer interference mechanics, and at best have achieved 9% to 22% reflection (in stark contrast to the "academic" exercises offered; although conforming to the treatment above). A MgF2+SiO double-layer coating shows better reflection characteristics in some parts of the BW, poorer in others. Overall this species averaged 8% (the two methods above exhibit flatter characteristics). The best achievement through careful selection of materials (MgF2+ZnS double-layer coating) obtained reflections on the order of 2% to 4%.

>
> You've missed the point entirely, the equation above already consigns
> 1.37mW to total darkness.

No, it doesn't. 1.37mW is the total reflection AFTER ONLY
ONE INTERNAL REFLECTION DURING THE TRANSIENT STATE. The
rest of the reflection is canceled by the subsequent
reflections. The steady-state equation is:

Pref1 = P1 + P2 + 2*sqrt(P1*P2)cos(180)

Pref1 = 111.1 + 111.1 - 2*sqrt(111.1*111.1) = ZERO

P1 = Pfor1*rho^2 = 1000mW*0.1111 = 111.1mW

P2 = Pref2*(1-rho^2) = 125*0.8889 = 111.1mW

Reflections are completely canceled during steady-state!!!
YOU missed the point entirely. I was merely pointing out
the mistake you made when you got 23.32mW after the first
reflection instead of the correct 1.37mW. The interference
during the transient state is not total. The interference
during steady-state is total.

One day God and St. Peter were having an argument. Suddenly,
God realized that St. Peter was right and He was wrong. God's
subsequent logic went something like this:

I am God. I am omniscient. I am incapable of being wrong.
Since I now know the correct answer, I must have known it
all along. Since St. Peter was previously arguing with me,
St. Peter must have been wrong all along.

Now replace "God" in the above with "Jim Kelley" and you will
get a picture of what has been happening with our postings.

To the best of my knowledge, the only argument we have left
is whether there is enough time for wave cancellation to
actually take place. We agree on virtually everything else
technical.

I appreciate your comments very much; clearly you have had a lot of experience with antennas. There was one question in my mind about aluminum siding in contrast to plain aluminum; it is my impression that aluminum siding is anodized, and anodized aluminum is an insulator. If my impression is correct, would that make any difference in the interaction between a loop and the siding?

Only the surface anodizing is an insulator. Radio frequency-wise, it
may just as well not be there leaving the high conductivity aluminium
siding to behave as if the anodizing didn't exist.

If the siding was covered with a 3" layer of plastic it still wouldn't
make any difference.

You mean that bit about how you think the waves first move in the reflected direction a little tiny bit and THEN cancel? Yes, you do need to rethink that. If they're equal in amplitude and opposite in phase, there's cancellation - at any value of t. In other words, the waves are prevented from reflecting. They don't reflect first, then disappear.

"Well, given the tremendous correspondence that attended the other threads, dare I pause to offer something from the realm of the real?"

If you don`t want an EM reflection in space, the possible reflecting object must be indistinguishable from space. It must have a resistive characteristic impedance of 377 ohms.

377 ohms per square material spaced 1/4-wave from a reflective surface for the purpose of completely absorbing a normally incident wave was invented by Stanfield Salisbury at the Harvard Radio Research Laboratory during WW-2, according to the 3rd edition of Kraus` "Antennas" on page 909, attenuation is at least 20 dB for the reflection and the bandwidth is 1.3 to 1. Kraus gives a transmission line equivalent diagram on page 910.

Kraus derives the 377 ohms of free space on page 131. The reflecting surface does not need to be zero or infinity ohms. The exposed surface must be transformed to 377 ohms from whatever the underlaying surface is.

The 377-ohm carbin cloth shown by Kraus is named Salisbury screen for its inventor. It is placed 1/4-wavelength from the reflective surface. The small amount of energy penetrating the screen undergoes 180-degrees of delay in makind a round trip to the reflective surface and back to the carbon screen. It undergoes an additional 180-degrees of delay in peflection. The 360-degree total puts the reflected energy back in-phase with the penetrating energy. This makes a high impedance.

A high impedance in parallel with 377 ohms leaves the 377 ohms unchanged. It continues to match the incident energy and continues to take a bite out of the reflected energy between the two surfaces.

Stealth aircraft, antenna laboratory. or non-reflective glass must look like 377 ohms.

Best regards, Richard Harrison, KB5WZI

A landmark in r.r.a.a history ladies and gentlemen. Cecil Moore says he agrees with Jim Kelley. Let me wipe a tear from my eye and cherish this moment. Of course "I agree" was in quotation marks and the agreement lasted just long enough for him to type those four words. He then continued arguing and badgering his hapless correspondent. :-(

No birch flogging necessary! He/she is right, though. This is a public forum, and it helps if the thread of conversation is succinct, but complete. Even if "Fear of Opinions" (is the mere presence of such a userID contrary to USENET?) didn't exactly give you any useful information, the main complaint might be that your public thread did not offer much more, simply because of the format.

For what it's worth, I was actually interested in the original post, but was not able to follow the thread without difficulty.

Once could think of this in a different way: English speakers have many ad hoc rules they adhere to when conversing with other English speakers. There are many shared notions of communication that are outside of official grammar that we stick to to maximize understanding. Written communication is no different, except that specific situations like USENET may require a closer set of specific ad hoc rulesets.

Things like bottom posting and obvious, succinct quoting just help everything work better. Well, it helps in cases where the participants are not spoiling for a fight.

Hi Richard,

This was EXACTLY the design goal obtained by NREL with their diffusion of a gradient of pores through the depth of the active surface. The variation of the index of refraction went from 1.0 to 3.5 with a smooth curve (albeit one jag at the beginning which reflects - seems only armchair designers can do it right).

>377 ohms per square material spaced 1/4-wave from a reflective surface

And this is roughly the technique employed by diffraction techniques which are superior to the quarterwave designs. The purpose is to contain the energy within the active matrix.

It appears your news server truncates the Topic line, starting a new thread each time - at least on my reader, I've noted that Google sews the threads back together tho'.

If they don't reflect first and then disappear, they don't exist
at all. But we know that reflected waves indeed exist and through
deduction can see how they must exist or else cause-and-effect is
violated. So your assertion that they never existed in the first
place is riddled with contradictions that I am unable to resolve.

So I ask again for the umteenth time. Given the rearward-traveling
reflected wave from the mismatched load encountering the match point,
exactly what turns that energy and momentum around and causes it to
flow back toward the load in the opposite direction? If not wave
cancellation, then what?

You simply cannot have it both ways. If the canceled waves don't
exist before they are cancel, they never existed at all and
therefore wave cancellation cannot exist at all. What you propose
is clearly a violation of cause-and-effect.

Hey Cecil,

The superposition of waves which are equal in amplitude and out of phase equals zero at any time t. There is no time t in the steady state when reflected waves to the left of the discontinuity can exist. The whole point of the exercise is to prevent reflections. You're proposing that the reflection is first allowed, and then it gets cancelled, but not really cuz then it has to turn around somehow and go back the other way. Let it drop man.

I agree and have never said they could. However, they do exist *at*
the impedance discontinuity, the point at which they are canceled.
To say the terms in the S-parameter equations don't ever exist in
the first place is ridiculous. That throws the entire S-parameter
analysis out the window.

> The whole
> point of the exercise is to prevent reflections. You're proposing that

It is a no-brainer to know that all energy heads toward the load
because everything heads toward the load at the match point in
a matched system. Reflections are prevented by the cancellation
of two reflected waves. If those two reflected waves never exist,
as you assert, how the heck can they engage in wave cancellation?
You are obviously violating the rules of cause and effect. It
is my understanding that can only happen at the quantum level
in physics. So you are in violation of the conventional laws of
physics.

Here's the question that you have avoided like the plague and
refuse to answer. Until you answer this question, your postings
are simply gut feelings.

Given the reflected energy wave from a mismatched load barreling
toward the source at the speed of light, what phenomenon of physics
causes the energy and momentum in that wave to reverse direction?

Hi Smitty....

I have used my MA-5B for over a year. I have it 40' up, and it works fine. It has withstood an ice storm this winter (1/4" ice build-up), and 60+ MPH winds a couple of times.

Highest gain is on 10 meters of course, but I've worked my fair share of DX on 20 and 15. Keep in mind that it functions as a 2-element Yagi only on 10, 15 and 20 meters. On 12 and 17 it is a rotatable dipole. Still, I'm happy with it. I've been able to work just about everything I've heard with it.

I assumed you knew. Reflection is caused when a wave encounters a
change in media of some kind.

Yep, you folks spend a fortune to get a bike 10 pounds lighter, then carry around a 20 pound chain to keep people from stealing it!

Every other sport takes place on a field designed for the sport. You guys for the most part ride on the highways creating a hazard.

What I am asserting and you haven't even come close to disproving is that wave cancellation of RF waves can cause reflections in exactly the same way as wave cancellation of light waves has been proven to cause reflections. What is it about the two following two technical reference quotes that you don't understand? Oh, now I remember. Your argument is that words don't mean what words mean. With that argument you can disprove anything.

www.mellesgriot.com/products/optics/oc_2_1.htm

"Clearly, if the wavelength of the incident light and the thickness of the film are such that a phase difference exists between reflections of p, then reflected wavefronts interfere destructively, and overall reflected intensity is a minimum. If the two reflections are of equal amplitude, then this amplitude (and hence intensity) minimum will be zero."

"In the absence of absorption or scatter, the principle of conservation of energy indicates all 'lost' reflected intensity will appear as enhanced intensity in the transmitted beam. The sum of the reflected and transmitted beam intensities is always equal to the incident intensity. This important fact has been confirmed experimentally."

http://micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index.html

"... when two waves of equal amplitude and wavelength that are 180-degrees out of phase with each other meet, they are not actually annihilated. All of the photon energy present in these waves must somehow be recovered or redistributed in a new direction, according to the law of energy conservation ... Instead, upon meeting, the photons are redistributed to regions that permit constructive interference, so the effect should be considered as a redistribution of light waves and photon energy rather than the spontaneous construction or destruction of light."

That's as clear as it can possibly be, Jim. Wave cancellation redistributes
the energy. In a transmission line, if energy is redistributed, it must
necessarily change directions. Would you believe there are only two
directions available in a transmission line? If not, please prove it.

Part of the problem may lie with how the average bicycle rider acts in some places. I am not assuming you are a bad guy, but I saw a bike rider folded in half laying in the street, yes he was dead, last year in downtown Minneapolis and I was pleased.

We have a nasty buch of assholes riding in our downtown. I had one kick by door becasue I didn't "yield" for him when I had the green light and he had the red.

Hi Fred,

You deserve a joke in return that is probably more entertaining than
mine I suspect.

From this week's Army Times is a comic strip by Mort Walker's "Beetle
Bailey." Beetle and Zero are ambling along talking:

Beetle - What if you could see into the future and saw your life was
miserable?

Zero - I'd keep on plugging away.

Beetle - Really? Why?

Zero - Hey, the future could be wrong!

This strip probably won't appear in the civilian funnys until next
week however, Mort always gives the Army Times his work first.

Cecil, W5DXP wrote:
"What phenomenon of physics causes the energy and momentum in that wave to reverse direction?"

Suppose you have a 50-ohm coax that has a 25-ohm resistor across its load end. The incident wave traveling on the coax has too much voltage and too little current to supply the 25-ohm load.

As the load forces the incident voltage lower, energy is conserved by transfer of energy from the E-field to the H-field. Voltage generated in this energy transfer between fields is reversed in phase from that in the incident wave. Though current is increased in the too low load resistance, its phase is unchanged from that in the incident wave.

The reversed-phase voltage caused by the roo-low load resistance launches the reflected wave.

Guys,

Thanks for your replies so far.
The buzz/noise is irregular. Not always, and when it's there, it's not always audible on the same frequencies.
I am afraid it's something in the neighbourhood. Lots of houses around, so it probably won't be easy to find out exactly where it comes from.
I also hear it when I connect a simple wire as an antenna, so I think it's not a ground loop?
I made a recording of 1602 kHz. this afternoon. You can hear the buzz/noise there, although not as strong as previous times.
Maybe someone can tell more by listening to the audioclip?
It is at http://mark-veldhuis.nl/1602.mp3 .

What I was talking about is a little more complicated than
that. Assume rho^2 = 0.5 at an impedance discontinuity at
a match point. The rearward-traveling reflected wave sees
the impedance discontinuity at the match point and 1/2 of
the energy is reflected back toward the load according to
the rules of reflection. What reflects the other half of
the energy?

The 50 ohm coax on the source side of the match point refuses
to accept *any* voltage or current. 100% of the reflected
energy is re-reflected at the match point.

Cecil, W5DXP wrote:
"What reflects the other half of the energy?"

The previous example I gave was a 25-ohm resistor-load on a 50-ohm line. Change the load to 100 ohms. Now the load cannot accept all the current carried by the incident wave. Lenz`s law says the falling current generates a rising voltage in an attempt to maintain the current. The load-generated voltage is in the same phase as the incident voltage so their sum is greater. Increased voltage across the load reverses phase and direction of the line-current at the too-high load resistance. Thus, direction of the reflection is opposite that of the incident wave.

If the load is too small or too large for Zo, some of the incident energy is reflected by the load. The two processes are analogous. When the load value is too small, there is a reversal in the phase of the voltage without change in the phase of the current (1955 Terman page 92). When the load value is too large, there is a reversal in the phase of the current without change in the phase of the voltage (1955 Terman page 89).

Those are the necessary and sufficient conditions to reverse the direction of some of the energy in an incident wave on a transmission line. For a complete reversal, a short or an open is required.

Best regards, Richard Harrison, KB5WZI

>It is at http://mark-veldhuis.nl/1602.mp3 .

Hi Mark,

I listened several times and it sounds like white noise with maybe a
hint of programming. However, that is the problem with noise, hearing
"things." I would not call it buzz at all.

There also appear to be two weak and broad resonances, but this is
from the crude spectrum presented by the WinAmp display. I used to
have spectrum analyzer software that would give a waterfall display
that would be useful in this situation, but I no longer have it
installed.

That aside, it actually sounds quite normal except I would expect some
broadcast activity near that frequency there in the low country.

What you say happens at a load is entirely correct. At a load, there is only one EM wave incident upon the load. But at an impedance discontinuity in a transmission line with reflections, there are two EM waves incident upon the impedance discontinuity, one from each direction. There's a forward wave coming from the source and a reflected wave coming from the load.

It might stand to reason that twice as many incident waves might complicate things beyond what happens at a load. And things are more complicated as can be observed from the s-parameter equations. For a single load, the s-parameter reflected voltage/power equations reduce to:

b1 = s11*a1 for normalized reflected voltage, and

b1^2 = (s11*a1)^2 for reflected power where s11^2 is the power reflection coefficient

For an impedance discontinuity in the middle of a transmission line with reflections, the s-parameter equation for normalized reflected voltage is:

b1 = s11*a1 + s12*a2 for normalized voltage, and

b1^2 = (s11*a1 + s12*a2)^2 for reflected power

It's pretty obvious that the reflected power equation at the impedance discontinuity is more complicated than the reflected power equation at the load. In fact, if you do the squaring of the right hand side of the equation just above, you get the interference term.

2*s11*s12*a1*a2*cos(phi) where phi is the phase angle between phasors a1 and a2.

The interference term, in watts, represents the amount of interference present and affects the magnitude of the reflected power. Since the amount of interference affects the total reflected power, it must also affect the total forward power so as to satisfy the conservation

of energy principle. Since interference affects the
magnitudes of both the reflected power and forward power,
the conclusion is inescapable that interference can also
cause reflections and this is verified by a couple of
technical web pages pertaining to light waves.

www.mellesgriot.com/products/optics/oc_2_1.htm

http://micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index
.html

Walter Maxwell wrote about such back in the 70's. From
Sec 4.3 of "Reflections" speaking of match points:

"The destructive wave interference between these two
complementary waves ... causes a complete cancellation
of energy flow in the direction toward the generator.
Conversely, the constructive wave interference produces
an energy maximum in the direction toward the load, ..."

In a transmission line with only two directions, when the
energy flow is canceled in one direction, that energy must
necessarily flow in the only other direction available, i.e.
an energy reflection must take place.

So to your list of three things that can cause 100% reflection,
you can add wave cancellation in the form of total destructive
interference between two EM waves traveling in the same direction
in a thansmission line, having equal magnitudes and opposite
phases.

Since you're the only person in history to have ever claimed such a
phenomenon occurs, the responsibility rests squarely with you to prove
it exists. As I just got done saying, the only way for electromagnetic
energy to change direction is by reflection. It seemed you understood
that.

> What is it about the two following two
> technical reference quotes that you don't understand?

I understand them perfectly. You may recall that I introduced you to
the Melles-Griot site. You on the other hand, misunderstand them.

And you are clearly reading more into it than it clearly says (as
evidenced by the fact that what you wrote and what it says are clearly

not the same thing). Your interpretation is totally incorrect. Interference is an effect not a cause. The text desribes the actual end result, but you're interpretting it to be a allusion to some sort of bizzarre supernatural phenomenon. You're better off doing what I have done. Figure out how it works by relying upon natural phenomena for the explanation. It works out beautifully if you'd at least give it a try. True, you won't be able to claim to have invented it. But claiming to have invented the other thing would probably only have earned you a "Cranky" on crank.net anyway.

snip

There's another way of viewing the manner in which energy reflected from a mismatch load. That is 'motor generator action'. Lest you think I'm joking, please let me quote from my own writing in QST August 1973, 32 years ago, repeated in Chapter 3 of Reflections 1 and 2:

"... Now we'll proceed to the generation of reflections. When the electromagnetic field reaches the end of the line, if the load terminating the line is an open circuit, the magnetic field collapses because the current goes to zero due to the infinite impedance of the open-circuit. The changing magnetic field at the open circuit produces a new electric field equal in energy to the magnetic field, which induces a new voltage into the load circuit that is equal to, and in phase with the voltage in the forward wave. (Keep in mind that a voltage is induced, or generated, by mutual motion between a magnetic field and a conductor, a phenomenon generally known as motor-generator action. Thus, it can be said that the reflected voltage was developed and delivered by a generator, a reflection generator. Although in this case the field is changing while the conductor is stationary, as in a transformer, it is motor-generator action nonetheless.) The new electric field induced by the changing magnetic field adds in phase to the existing electric field, and the new induced voltage (delivered by the reflection generator) adds in phase to the voltage in the forward wave, resulting in an increase of voltage at the open circuit to twice the voltage of the forward wave. At this instant, a standing wave is developing, because now there is a current minimum and a voltage maximum at the open-circuit termination, where an instant before, current and voltage were constant all along the line.
The new voltage at the open-circuit termination, along with its new electric field, starts a voltage wave traveling in the rearward direction, as if it had been launched by a separate generator at the open-circuit point. (It has---remember the induced voltage, generated by the changing magnetic field?) Since no energy was absorbed by the open-circuit load, the new rearward-traveling voltage wave has the

same magnitude as the original forward wave, which is why rho = 1, indicating total reflection. As the new electric field starts its rearward travel, it produces a new magnetic field, which in turn produces a new current, launched into the line as the reflected current wave with the same magnitude as the forward current wave, but with opposite polarity and direction. The new electric and magnetic fields combine to form the reflected electromagnetic field and, as in the forward electromagnetic-field wave, the energy in the reflected electromagnetic-field wave also divides equally between its electric and magnetic fields."

I have quoted many references. That you choose to ignore them is
not my problem. Of course, they are not going to use identical
words to mine. Ham radio lingo has a flavor all it's own,
"reflections" being one of them. I am expecting any moment for
you to say a reversal of energy flow in a transmission line is
not always a reflection. That's how you resolve arguments - by
redefining words until your opponent is wrong, by definition.

> As I just got done saying, the only way for electromagnetic
> energy to change direction is by reflection. It seemed you understood
> that.

I certainly do and wave cancellation can cause a reflection,
i.e. a reversal of energy flow in a transmission line. It's
as simple as that. The "redistribution of energy in a different
direction" caused by wave cancellation can only occur in one
direction in a transmission line. If wave cancellation occurs
in one direction, the energy existing in the waves before they
were canceled must necessarily be distributed in the only other
direction possible. It's all explained on the optics web pages
that I previously posted.

> I understand them perfectly. You may recall that I introduced you to
> the Melles-Griot site. You on the other hand, misunderstand them.

When you introduced me to the Melles-Groit web page, you told
me what it said and I still think you were right. You were happy
for me because you had found something to support my concepts. After
a few days, you changed your mind and informed me that it didn't
say what you first thought it said. Maybe you should question what
caused your mind to change? Quite often, the first conclusion is the
correct one. So does it say what it says, or not?

> And you are clearly reading more into it than it clearly says (as
> evidenced by the fact that what you wrote and what it says are clearly
> not the same thing).

Clearly not identical but clearly meaning the same thing as
you said it meant when you first introduced me to that web page.
Why did you change your mind about what it said?

> Your interpretation is totally incorrect.

Then your initial interpretation of the Melles-Groit web page
information was totally incorrect. Why did you do a 180?

> Interference is an effect not a cause.

Interference is not an end effect. Interference can cause the
perception of light and dark rings on the human retina. Lots
of effects which have a cause, cause additional effects in
a chain of cause and effect events. Haven't you ever seen
the TV series "Connections" where one effect caused another
effect which caused another effect ...? So the spacing of the
wheels on a Roman chariot eventually dictated the maximum size
of the boosters on the Space Shuttle?

Interference in transmission lines can cause reflections which
is simply a redistribution of energy in the only other direction
possible. What is it about the "redistribution of energy caused
by interference" that you don't understand? It is explained on
those web pages. In a transmission line, dispersion and refraction
are mostly absent, so reflection is the only thing that can
possibly "redistribute the energy". We know the reflected energy
stops flowing toward the source in the transmission line at a
match point. Wonder what other possible direction it can take next?
That's a really tough question. ... I like you, Jim, because you
make me laugh.

I know intimately well what caused me to change my mind. It doesn't make sense! It's insupportable by the underlying physics. I work in the field; I've asked E&M people about it. I didn't make up an explanation for this - YOU DID! Then you looked around to see if it was true. And you want to think that Melles-Griot confirms it. But it doesn't.

> Quite often, the first conclusion is the

My second conclusion enjoyed the benefit of actually working through the problem. That's certainly not true in your case.

You have no idea what you are talking about. You are making a fool of yourself. Since you don't believe me, try to get Melles-Griot or Eugene Hecht to confirm your theory that interference causes waves to reflect. Good luck with that OM.

That's just your opinion, worth exactly what it costs. You have
presented no technical argument to prove your case. All you have
presented are logical diversions, personal opinions, and gut feelings.

Why do you refuse to answer the question: Given reflected energy
rejected by a mismatched load, what causes the reversal of direction
of the energy flow and momentum at the match point? It is a simple
question that you have avoided answering for months. One wonders why.

> You have no idea what you are talking about. You are making a fool of
> yourself.

Asserting that there is no before and after is foolish. Asserting
that a redistribution of energy in a transmission line must have
more than one choice is foolish. Implying that cause and effect
doesn't exist is foolish. Asserting that the waves involved
in wave cancellation don't exist is foolish.

If the waves involved in wave cancellation don't exist, then
wave cancellation is impossible. That's simple logic. If wave
cancellation doesn't exist, it follows that the energy flowing
toward the source is not zero even though we measure it at zero.
This is the logical hole that Dr. Best dug for himself and you
crawled right in after him. Dr. Best asserted that the two waves
keep flowing toward the load, canceling each other all the way
to somewhere (or nowhere). The concepts that you hold concerning
this subject are proven to be logically contradictory. You may
disagree, but I don't believe contradictions can exist in reality.
I believe they can only exist in human minds and yours obviously
contains a multitude. When I encounter a contradiction, I change
my mind. You obviously tolerate (and seem to enjoy) contradictions.
You even use contradictions as part of your arguments.

3958. Open ladder line question

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-05 22:03:32 UTC
From: "S.Fritts" <w4sef@att.net>
Message-ID: <cao7f1lr66o1g2ob65ad8f9dun6v8s83ej@4ax.com>
Source record: 72076

In reference to the discussion about the fellow wanting to run several antennas with seperate ladder lines, is it ok to terminate the ladder line with a 4:1 balun and the run the coax from the balun to the tuner? I also want to run at least two center fed zepp type antennas fed with ladder line. Can I just terminate the ladder lines outside with a 4:1 balun on each and run two coax feed lines to an antenna switch inside the house?

I hope I am making myself clear on this.

Thanks

Steve W4SEF

3959. Feeding ladder line question

Hi Fritts:

Yes you can do that, why not? I would try and keep the coax run as short as possible because with a center feed zepp on most frequencies the SWR on the coax will be very high and the extra loss from the high SWR will eat up some of you power.

Hafta be kinds careful around here. Many Police Departments use officers on Bicycles. It's much more difficult to munch a donut, hold a coffee and pedal uphill.

Yes, bicyclists do have fatal accidents. I wonder if bicycle mobile is a contributing factor?

> of the energy flow and momentum at the match point?

The only thing which can cause energy to change direction is reflection. I have answered that question every time you asked it. Perhaps you were just unable to grasp the meaning of the answer. It means that for an electromagnetic wave to reverse direction, it must encounter a change in the nature of the conducting medium.

Interference results when two or more waves superpose. The pattern is the amplitude resultant plotted as a function of position. It may be generated as a result of a reflection, but is not an entity which itself reflects waves. Impedance discontinuities or changes in the index of refraction - those things cause reflection. An interference pattern created by waves is still just waves arranged differently. Waves don't cause other waves to change direction. If you think they do, then you need to try to find some proof. Adding your misguided editorials to desriptions of interference doesn't qualify.

Cecil, W5DXP wrote:
"What phenomenon of physics causes the energy and momentum in that wave to reverse direction?"

It must keep moving and if it can`t go somewhere it goes elsewhere.

Shorts and opens are a way to control current which in its magnitude, phase, and path produces fields.

In a transmission line or wave guide, waves are guided. In free-space, waves move away from the source.

In a small single-turn loop, the current everywhere within the loop is very nearly the same. A complete null is achieved on the axis of the loop (see 3rd edition of Kraus` "Antennas" page 204, Fig. 7-7).

The loop`s null results from equidistance along the axis srom corrent and fields which are in opposite directions. The fields are moving in the same directions but because of their opposite polarities add to zero along the axis.

So, to opens and shorts, equal and opposite radiation fields can be added to the list of things which cancel energy traveling in a certain direction. When a fixed rate of energy flow must be maintained, cancelled energy must emerge in the noncancelled directions. It`s energy conservation.

Best regards, Richard Harrison, KB5WZI

Hmmm, an infinite reflection problem.

This certainly must be the single place precision proof for having
enough energy not to cancel anything.

C'mon guys, dress it up with some style or humor, otherwise it is like
watching C-SPAN with two politicians spitting at each other in an
empty chamber of congress. :-)

Jim Kelley wrote:
> The only thing which can cause energy to change direction is reflection.
> I have answered that question every time you asked it.

But that is a non-answer and you don't offer any idea as to the cause
of the reflection. What causes 100% re-reflection of reflected waves
in a matched system? You are still avoiding a valid answer.

> It means that for
> an electromagnetic wave to reverse direction, it must encounter a change
> in the nature of the conducting medium.

Assume it encounters a power reflection coefficient of 0.5 in a
matched system. What causes the reflection of the other half of
the reflected energy?

> Impedance discontinuities or changes in the index of
> refraction - those things cause reflection.

Yes, and wave cancellation in a transmission line only happens at
an impedance discontinuity so your assertion has no point.

> An interference pattern
> created by waves is still just waves arranged differently.

On the contrary, wave cancellation at a match point is permanent.
The waves cease to existence in the direction of the source. They
are not arranged differently. Your assertion is obviously false
for interference patterns at match points in transmission lines.
Before you go into a tirade, what you say is usually true, just
not for match points in transmission lines which is a special case.

> Waves don't cause other waves to change direction.

Normally, that's true. But when the two coherent waves disappear
from existence in the direction of the source, the conservation
of energy principle takes over. If the energy is not flowing
toward the source then it must necessarily flow toward the load.
That is such a simple concept it's hard to believe that you
cannot comprehend it. It's explained in the web page quote below.

> If you think they do, then you need to try to find some proof.

Isn't the following proof enough? They are talking about wave
cancellation such as happens at a non-reflective surface or a
match point in a transmission line.

"... when two waves of equal amplitude and wavelength that are 180-
degrees out of phase with each other meet, they are not actually
annihilated. All of the photon energy present in these waves must
somehow be recovered or redistributed in a new direction, according to
the law of energy conservation ..."

"Redistributed in a new direction" in a transmission line means
changing direction. What is it about that simple concept that
you fail to comprehend?

> added to the list of things which cancel energy traveling in a certain
> direction.

Thanks Richard, that's what I have been trying to say. And the
"equal and opposite radiation fields" can occur inside a
transmission line at an impedance discontinuity. After all, an
RF transmission line signal is just EM wave-fields contained
by a boundary.

Walter Maxwell said such in "Reflections II", page 23-9:
"With equal magnitudes and opposite phase at the same point
(Point A, the matching point), the sum of the two waves is
zero."

When two waves sum to zero, their energy components must be
redistributed. In a transmission line, if energy ceases flowing
in one direction, it must change directions. That's a reflection.

So here's a list of things that can cause 100% re-reflection of
reflected energy in a transmission line. 1. short-circuit,
2. open-circuit, 3. pure reactance, 4. permanent wave cancellation
at an impedance discontinuity.

Source record: 72094

Hi
I have just got planning permission for a 75 Foot tower. I plan on putting a Force 12 C31 XR (10-15-20) as well as a lightweight 50MHz and 144MHz yagis, and a rotable 7MHz Dipole up.

I plan on running top band by using a Gamma match to feed the tower against a good carpet of buried radials and a chicken wire mat.

My question is, does anyone here have experience of shunt feeding a tower for top band, and, does anyone have a formula for calculating the match ? What are you experiences, how good is the solution ?

(The formula is important as it will determine the type of tower I order, in terms of seftion length as I don't want to order a tower that although telescopic, has the gamma match feed pint half way up a telescoping section).

Thanks

Adrian Rees
M1LCR

Date: 2005-08-06 13:07:01 UTC
From: TOM <noname@noprovider.nodomain>
Message-ID: <VB2Je.2885$iE.237@trnddc06>
Source record: 72098

Hi Adrian,

The feed point will depend on the geometry of the gamma match wire.
A large cage requires a shorter gamma wire than a thin gamma cage.

For my tower, a 6" diameter 3-wire cage spaced 2-1/2 feet from the tower
was about 34 feet high at the 12.5 ohms point. It was replaced with a 1"
diameter
aluminum tube and the feedpoint moved up to 42 feet high at the 12.5 ohm
point.
This is for topband. The wire cage kept breaking due to wire fatigue (we
have a lot
of wind here), the aluminum tube is much more reliable.

The 12.5 ohm feedpoint at 1850 KHz turns out to be a 50 ohms feedpont
at about 3750 KHz. Using a 4:1 transformer, one can thus select this gamma
feed for either 160 or 80 meters.

A 50 ohm feedpoint on topband would be *rougly* twice the lengths quoted
above.

The gamma capacitor is a 15 kv vacuum variable with a homebrew stepper motor
to turn the capacitor. Tuning the capacitor allows full coverage 1.8-2 MHz.
and 3.5-4 MHz.
An assortment of wide-spaced air variables all arced badly at 1.5 KW power
level.

I'm thinking of getting a Buddipole antenna.
I would loke comments on that antenna.
Thanks.
VE2ATD

3982. Looking for Butternut HF9V

Hi all,

I am looking for a used Butternut HF9V vertical. If you do, please reply to this message. Remove the "ZZZ" from my E-mail address.

Thanks,

RON KA2IIA

3983. A Simple Conceptual Example in Discussing Thin Layer Reflections

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-06 18:45:26 UTC
From: Richard Clark <kb7qhc@comcast.net>
Message-ID: <c90af1t3auroiviiuglvtdps6h2h2geju8@4ax.com>
Source record: 72101

Returning again with a new example, described in text as:

1w | 1/4WL | |/
laser-----air-----|---Si Crystal---|---Al contact--- |/
1st medium | 2nd medium | 3rd medium |/
n = 1.0 n = 5.8275 n >> 6

where:
the laser is in the UV/deep Blue (355nm to 360nm)
the second medium is a single crystal of Silicon
the third medium is a reflective aluminum contact.

When you take the intensity times the area for both the reflected and
refracted beams, the total energy flux must equal that in the incident
beam. That equation appears as:
(rï¿½ + (tï¿½ ï¿½ n2ï¿½ ï¿½ cos(theta-t) / n1ï¿½ ï¿½ cos(theta-i))) = 1

It stands to reason that this can be quickly reduced without need to
use transcendentals for an angle of incidence of 0ï¿½ (which results in
a refractive angle of 0ï¿½). All that needs to be known are the
coefficients which for that same angle simplify to
r = 0.7071 a value that is the limit of an asymptote;
it is also invested with either a + or - sign depending
upon the polarization (another issue that was discarded
in the original discussion as more unknown than immaterial)
t = 0.7071 a value that is the limit of an asymptote;
here, too, there are polarization issues we will discard as
before. All this discarding comes only by virtue of squaring:
rï¿½ = 0.5000
tï¿½ = 0.5000
I presume that the remainder of the math can be agreed to exhibit:
that part of the energy reflected amounts to 50%
and that part of the energy transmitted amounts to 50%.

In this example (a farrago, to say the least), it is overwhelmingly
obvious that when the incident energy strikes the first interface that
half of it is reflected and half of it transmitted (a common
specification for this specie). Even more obvious is that the sum
total of all re-reflections between the interfaces (and it has been
absurdly guaranteed that no energy will ever transit the aluminum
mirror) will combine in the proper phase relationship to "totally"
cancel the first reflection.

Now, what to make of this black mirror? The same conservation of
energy has been maintained as has been exhibited in other threads of
this ilk. That conservation expressed above as both a commentary and

a formula is satisfied and "total" cancellation has been presented.

To wit, and in former expressions:

Observing the conservation of energy at the first interface:
X = 0.5000X + 0.5000X
Observing the conservation of energy at the second interface:
0.5000X = 0.5000X + 0.0000X

0.5000X == 0.5000X

Of course, to put the lie to this example, no mirror is completely reflective. Some in these "debates" wanted to inject loss, or the lack of perfection. This should satisfy those who need this smudgy focus.

To brush aside those anticipated rejections requires only expressing what fraction the "best" mirror could provide, and simple trim the wavelength of the source to match the numbers. Let me offer:

We have a mirror that is only 98% reflective (it would exhibit a refractive index more than 1000 in this example). By slipping the wavelength 2nm shorter (actually there are other wavelengths that support these indices, but this is as illustrative as any); then we can allow for 49.5% reflection, a 50.5% transmission, a subsequent summation of all reflections with the 98% mirror to once again exhibit:
Observing the conservation of energy at the first interface:
X = 0.495X + 0.505X
Observing the conservation of energy at the second interface:
0.505X = 0.495X + 0.010X

0.495X == 0.495X

Choose another mirror efficiency and one need only perform like wavelength adjustments to obtain the necessary energy.

As I've offered in other posts, the "total" cancellation is entirely driven by very simple optics which resolve to obvious ratios in the expression of conservation of energy.

And, of course, "total" is not. ;-)

Even with this pencil-whipping out 4 places, the reflection products that remain (in the 5th place) in this example are vastly brighter than the sun (for those who see this wavelength). Also note that the complete exercise reveals through the conservation of energy that there is a loss (due to the incomplete reflection of the in-efficient mirror) and that all energies add to the energy applied to the system.

Uhhhhhhh Richard, that is not a matched example so, of course,
there is no total cancellation of reflections. Why do you
think a mis-matched system would ever have total cancellation?

What can we do to make it a matched example?
Make n3 = 5.8275^2 = 33.93. I have no idea what medium 3 is
made out of but it also has to reflect 1/2 the energy incident
upon its surface. Now the reflectance (power reflection coefficient)
equals 0.5 and is the same at discontinuity A as it is at
discontinuity B. The 3rd medium will be considered to be infinite
for purposes of simplicity.

1w 1st medium | 1/4WL |
laser-----air-----|---2nd medium---|---3rd medium--->...
n = 1.0 | n = 5.8275 | n=33.93
A B

Now it is matched and reflections are totally canceled. The
forward power in medium 1 is 1W. The reflected power in medium 1
is zero. The forward power in medium 2 is 2W. The reflected
power in medium 2 is 1W. The forward power in medium 3 is
1W. The reflected power in medium 3 is zero.

The above example is akin to the following transmission line
example with identical forward and reflected powers.

1/4WL
1W XMTR---50 ohm line---+---291.4 ohm line---+---1698 ohm load
A B
Pfor1=1W--> Pfor2=2W--> PL=1W
<--Pref1=0W <--Pref2=1W

This is a Z0-matched system with no reflections on the 50 ohm
line. The fact that half the power is reflected at each discontinuity
makes it easy to calculate and recognize.

****
In a lossless matched system where half the power is reflected at each
discontinuity, the forward power in medium 2 will be exactly double
the forward power in medium 1.
****

Please read that over until you understand it and then try to figure
out why. Hint: it is not a violation of the conservation of energy
principle. Soon the hole you have dug for yourself will be so deep,
you won't be able to reach your keyboard. :-)

>of the coax cable?

Jim Tonne, WB6BLD, wrote a program in Visual Basic that does
precisely that for all common tuner configurations. It is
called Revload and can be downloaded for free from:

http://www.tonnesoftware.com/revload.html

You may want to check out his other ham-radio related programs,
listed on his main page:

http://www.tonnesoftware.com/

As others have pointed out, this is not a particularly accurate
way of measuring impedance, but it should be adequate for "ballpark"
estimates.

Message-ID: <dd4vgohhd1@nwrdmz01.dmz.ncs.ea.ibs-infra.bt.com>
Source record: 72116

Hi Tom

Thanks very much for the information. Well, I have done some calculations, and gert a very similar result.
My calculations are based upon a 4 wire Gamma cage, consisting of 4 wires, each made up of 7 strands of 0.5mm wire. (The sort of stuff you can get in the UK that electricians use for lighting). Each of the 4 wires are insulated. These are held in a box secton (wire at each corner) by a copper plate spacer. (1.5mm 6 and a half inch square copper plate). Each wire is soldered to the corners of the copper plate, and each plate is spaced 3 feet apart. So effectively the match becomes a 6 inch square copper bar. (well near enough).

Spacing this like yours at 2 and half feet from the tower shows a Gamma match point at 28 Feet. This is getting close to what I want at 26 Feet, (Bottom section of the Tower is 26 Feet high and I want to be able to lower the tower, without unhooking a gamma section.)
I'll rework the calculations with 8 wires and see if that lowers the height, if not I'll try different spacing.

(I often get called away urgently and the XYL may need to lower the tower. The simpler it is the better. Ie don't want her to have to unhook a Gamma match, then do X, then Y then lower the tower, you get my drift?)

Thanks Again

73

Adrian M1LCR

4002. Hazards of raised radials

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-07 15:31:21 UTC
From: ricknj10@hotmail.com
Message-ID: <42f626da.87154906@news.optonline.net>
Source record: 72120

Regarding the potential hazards involved in using raised radials on a vertical - I'd be interested in comments from readers of this newsgroup.

The antenna installation proposed is a vertical installed through the roof of a building. For many reasons it would be preferable to keep the radials inside the attic. My concern is possible danger due to the high voltages incurred at the ends of the radials. The antenna will be a SteppIR vertical for 40-10 meters with the base just under the roof, protruding through the roof. At the base will be a number of resonant radials fanning out throughout the attic. My concern is if this poses a fire hazard due to arcing (corona, whatever) at the ends of the radials. It may not be convenient to suspend the radials over their entire length or provide high quality suspended insulators at the wire ends. So what danger is there in letting radials lay on the floor of the attic, attached to the roof rafters, or even poked down inside the studs of the walls? I think we can assume the attic will be dry, except for normal Seattle humidity !!

As a followup to my question, I guess the concept or the question is no different than if it referred to a dipole instead of radials on a vertical. The concern is protection from the high voltage at the end of the wire, and the potential of it causing a fire.
So it is really a very general question, considering the numbers of antennas hams are having to disguise or hide inside their homes these days.

Unless you run kilowatts you have nothing to worry about. To be on the safe side. just use thick plastic covered wire for your radials taking a little extra care at the extreme ends. Inspect every few years.

If by some very remote chance arcing should occur your SWR meter will jump about and you will be obliged immediately to investigate whatever is the cause, radials or anything else.

Rick, You are welcome.

I have on occasion, for educational reasons and to avoid the many misunderstandings, recommended a change in the name of the ubiquitous SWR meter. It does not measure SWR and usually there is no line on which the SWR purports to be measured. And reflected power is somewhat meaningless or at least useless information.

However, where it is located, it is an extremely valuable indicating instrument. I have suggested the name be changed to TLI (Transmitter Loading Indicator) which it actually is. Unfortunately, there are too many old wives in the way and it interferes with their ancient, pre-1950 traditions.

In a vertical dipole, you have only one "radial" which carries
the same currents and voltages as the upper vertical element.
Seems to me, when one has multiple radials, the energy in each
radial has to be the total energy available divided by the number
of radials. Therefore, the voltage at the ends of 1/4WL radials
should decrease as the number of radials is increased.

This seems to be another way that distributed networks differ
from lumped circuits. We might even be able to calculate the
voltage at the ends of the radials, given the number of radials
and the total power available to the radial system.

Hi,

OK, 1 more clip. I know I could try to find the source of the noise by using as portable radio + loop antenna, but my ALA is mounted on the shed and I have no other loop available. Maybe someone can identify a possible noise source by listening to the clip, or at least give more tips. If not, I'll try to walk around the neighbourhood with just a portable, and see what the results of that are.

The noise/buzz on this clip is stronger than on the previous one.

Thanks in advance!

Hi Mark,

This is more distinctive, and I have heard this before. I do not
think it is local noise, sounds more like jamming. In fact, it may
not be on the frequency you think it is, but rather is an IF image.

Try tuning around 910KHz higher (or lower) in frequency to see if you
can hear the same thing. (910KHz will only work if your receiver has
an IF of 455KHz)

Cec, don't you think you should take diameter of radials as well as their number into account. Also their angle, and the height above ground, or their distance from the brickwork, roof beams and rafters when in an attic.

Do you have an equation for Volts = Function(number, frequency, watts, length, diameter, angle, height, etc) ?

Actually, I was thinking free space when I wrote that. It
was a qualitative answer, Reg, not a quantitative one.

> Do you have an equation for Volts = Function(number, frequency,
> watts, length, diameter, angle, height, etc) ?

Only a ballpark figure, Reg, which should be good enough.
Since balanced radials don't radiate (much), it should
be a piece of cake for you to come up with a piece of
software that calculates voltage at the tips Vs number
of radials. Let me know if you need any help. :-)

Rick,
One thought - I'd be very concerned about RF getting into the entire house system, especially stereos and tv's, depending on how your "radials" align with house wiring and how proximate they are. I had a dipole 15 feet off the roof of my house and at 1 KW, it wasn't a pretty sight...burglar and fire alarms going off, night lights blinking (the KW is on a separate 220 line), stereo speakers talking donald duck...the whole house rebelled. So now I am repositioning it out in the back pasture. The only alternative is QRP!

The Buddipole is a short, loaded portable antenna. Works OK for camping, pedestrian mobile, field day, mobile and any number of other uses. I would not use it as my primary antenna at my home QTH.

I guess I asked the wrong question. Why do you think you
are dealing with a 450 ohm impedance? It's impossible to
encounter a 450 ohm impedance on a Z0=450 ohm transmission
line with reflections and one doesn't often encounter an
antenna with a 450 ohm feedpoint impedance.

Reg,

The 1937 Brown, Lewis and Epstein IRE paper "Ground Systems as a Factor in Antenna Efficiency" include an analysis of the currents in radial ground systems, along with equations and graphs for it in various configurations. All you need to do to apply them to a system of raised radials is to modify these basic equations.

Of course, you will have to read the paper first to do that (wink, nudge). But then you might also see why knowledge of ground conductivity was unimportant to the conclusions of this paper, and refrain from saying so in the future.

I have also explained the cause of reflection to you many times. (Hint:
it's the change in media thing. See below for one example.)

> What causes 100% re-reflection of reflected waves
> in a matched system? You are still avoiding a valid answer.

I wrote you an email with a reference that I recomended you read.
It's the best explanation I've seen. I'll bet you haven't read it. I
don't know why you keep saying I avoid these things when my efforts to
explain it to you is my entire purpose for corresponding on the subject.

>> It means that for an electromagnetic wave to reverse direction, it
>> must encounter a change in the nature of the conducting medium.
>
>
> Assume it encounters a power reflection coefficient of 0.5 in a
> matched system. What causes the reflection of the other half of
> the reflected energy?

The thing that causes reflection is a change in media. Impedance, index
of refraction - something like that. See below.

>> Impedance discontinuities or changes in the index of refraction -
>> those things cause reflection.
>
>
> Yes, and wave cancellation in a transmission line only happens at
> an impedance discontinuity so your assertion has no point.

Then it must be that your question, which I answered, had no point.

Unfortunately, the mathematical analysis in that paper was found to be in error. A search of the literature shows that quite a number of people worked on this problem well after publication of the BL&E paper. Some notable work was done by J.R. Wait and W.A. Pope of the Radiation Physics Laboratory, Defence Research Branch, in Canada. Two papers in particular give equations for the impedance of radial systems which appear to be valid -- "The Characteristics of a Vertical Antenna With a Radial Conductor Ground System", Appl. Sci. Res. B, Vol. 4, 1954; and "Input Resistance of L.F. Unipole Aerials With Radial Wire Earth Systems", Wireless Engineer, May, 1955. The equations involve multiple integral equations which can't be solved in closed form. In papers I've read which do involve equations which can be solved in closed form, even approximately, the results have deviated greatly from BL&E's measured results, making the accuracy of the method doubtful. This holds true for Reg's program, also, which apparently depends on some simplifying assumptions which aren't valid.

NEC-2, which is readily available in numerous forms, does about as good a calculation as any of elevated radial systems. Its major limitation, in my opinion, is the inability to deal with stratified ground. Of course, even if it could handle stratified ground, the user would somehow have to determine the properties and locations of the various strata. NEC-4 can, in addition to NEC-2's capabilities, include buried radials in its models. A few tests show reasonable agreement between it and BL&E's results. Incidentally, the equations in the first Wait and Pope paper I mentioned resemble those used in NEC-4, but I haven't studied them in enough detail to determine if they are indeed the same.

Elevated radial systems have been somewhat controversial, with some indications that modeled results don't imitate actual results very well, particularly at low frequencies. But there's very little really good measurement data available to make a valid judgement. Besides the possibility of stratified ground, some people have reported difficulty in maintaining equal currents in near-resonant elevated radial wires in real installations. This would have a substantial effect on a system, and would definitely cause deviation between modeled and measured results.

There's considerable work to be done in this field, but what really needs to be done is the making of good, well documented and carefully done measurements of elevated radial systems -- not more calculations based on invalid assumptions.

Hi Roy,

That inspired me to reach for The ARRL Antenna Compendium, Volume 2.

Within it, the very first article, is
"Vertical Antennas: New Design and Construction Data"
By Doty, K8CFU; Frey, W3ESU; and Mills, K4HU

Their 10M vertical(s) above an elevated radial system of 64 wires
presents some interesting results. Albeit, they perhaps do not answer
the questions you've offered, but it does reveal the quality of work
possible.

Hi OM,

In fact those authors took great care to consider the condition of
ground conductivity and documented it for very good reasons. One of
the hallmarks of their work reveals that the phase shift between the
RF in the Wire, and that induced into the ground causes the lateral
flow of currents, increasing power dissipation. This is a major
reason why the density and spacing are important.

Elevating the radials creates an entirely different situation.

4031. Antennas for Part 15 AM Stations (US)

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-08 20:37:07 UTC
From: Richard Fry <rfry@adams.net>
Message-ID: <42f7c2d6_4@newsfeed.slurp.net>

Under the line below is my response to the post of 'LH' on another website. The subject started when someone else posted that legal Part 15 AM stations can have usable groundwave coverage out to 5-10 miles.

Maybe some at r.r.a.a. might be asked to get involved with one of these stations at some point, and find these comments useful. Or not.

RF

+ + +

\\ LH wrote:
>Next time a non-D AM tower falls over, let's clean up the mess,
>then install a Rangemaster or other high quality Part 15 transmitter
>on the ground at the center of the radial system and see how far
>it gets out, measure the field strength, etc. The official 3 meter
>antenna to be used.

An interesting concept.

A 3-meter vertical radiator is ~3.6 electrical degrees at 1 MHz. Using Figure 32 in George Brown's paper I referred to in an earlier post, the FCC efficiency of such a vertical with a ground system consisting of 113 radials of 0.27 wavelengths each is about 40 mV/m at 1 mile for 1 kW of radiated power.

Using that efficiency with the FCC's AM curves for 1 MHz, and assuming that the Part 15 AM tx could supply 80 mW to the radiator,* here are the parameters for a ground conductivity of 8 mS/m:

2.00 mV/m 0.1751 miles
0.500 mV/m 0.6695 miles
0.100 mV/m 2.9125 miles

NEC-2 calculates a base impedance of ~ 0.04 -j6500 ohms for this set of conditions (4mm constant OD radiator). No practical transmitter could deliver its rated power into such an impedance, but we have ignored that for these calculations. (The reactance term can be cancelled by using a loading coil, but the required coil would absorb a large amount of the available power due to I^2R loss).

Considering that Part 15 AM stations using intentional radiators neither have the ground system described above, nor can cause the RF current equivalent to 80 mW to flow in the radiating portion of a 3-meter antenna, it is clear that any Part 15 "coverage" claimed that approaches or exceeds what is shown in the calculations above must be related to the use of an

illegal antenna system, and/or illegally high tx power.

* AM Part 15 limits the tx to 100 mW of input power.
Output power will be less -- 80 mW was assumed.

Source record: 72151

Gidday

Apologies for being the newbie in this. I'll admit I am after a quick fix!

Am playing with modelling a 20M single quad loop. Yes I have built one before with a 75r section and it works fine.

The problem I have is how to represent the 1/4 piece of coax on 4NEC2. A piece of transmission line seems to have to be connected to a "wire" at each end and I get an error if I just have one hanging in free space where the feedpoint is.

I am aware I can do it at the Smith Chart output but I'd prefer to be able to graph actual Z/SWR.

Thoughts?

Cheers Bob VK2YQA/WA5

You simply cannot hurl nasty, obscene, ad hominem insults and still
expect someone to read your emails. You cannot say you weren't warned.

>>> Waves don't cause other waves to change direction.
>>
>> Normally, that's true.
>
> As if you would know. It's of course always true.

It is, of course, not always true as proven by the quote from the
following web page. What is it about WAVE INTERFERENCE causing energy
to be "redistributed in a new direction" that you don't understand?

It clearly contradicts what you are asserting. It plainly asserts that
TWO INTERFERING WAVES can cause the energy in the two waves to change
direction. And it can only happen at an impedance discontinuity
which should be enough to satisfy your requirements.

"... when two waves of equal amplitude and wavelength that are 180-
degrees out of phase with each other meet, they are not actually
annihilated. All of the photon energy present in these waves must
somehow be recovered or redistributed in a new direction, according to
the law of energy conservation ... Instead, upon meeting, the photons
are redistributed to regions that permit constructive interference, so
the effect should be considered as a redistribution of light waves and
photon energy rather than the spontaneous construction or destruction
of light."

We are just going to have to agree to disagree on this one. But I do
believe that my references outweigh yours by a long shot.

That's obscene alright.

Maybe it was when I said that you're describing the match point as if it were a 100% reflective one-way mirror. A one way mirror is actually not a bad analogy. Problem is you keep insisting that it must be 100% reflective - which obviously can't work. I tried to explain that each reflection is only partial, but each wavefront subsequently experiences multiple reflections - each time reduced in amplitude by a factor of rho1*rho2 per round trip. And, that the total amplitude equals the sum of all previous undamped reflections, which happens to equal the 100% number. That's what is in the textbooks I referred to you. It's also what Walt explains in his 1/4 wave transformer diagrams.

If the truth is a vulgar obscenity to you, then I guess I might rightly be accused of "hurling" that at you.

Bob, I don't know much about quad loops, so not sure what you are doing. Is the 1/4 wave coax just to transform the single loop input impedance to a lower value? I think a loop has about 120 ohm input Z, so 1/4 wave 75 ohm coax transforms it to near 50 ohm.

The transmission lines in NEC are ideal, so you will not get any loss as with a real transmission line. You do have to have a piece of wire at each end. The loop end wire is the loop, and the feed point end wire must contain the NEC source.

Do I have the right idea, or am I completely out to lunch?

Regards,

Frank

Bob, you will note that Dan develops an approximation for the actual
characteristic impedance of transmission line rather than use the
nominal characteristic impedance.

The SWR figure is calculated for the estimated characteristic
impedance, and the SWR(50) is calculated based on a characteristic
impedance of 50+j0.

That is also what I have been saying and nothing I have said disagrees
with anything above. I have not introduced anything new. I have merely
tied a couple of loose ends together by bringing some well understood
concepts over from optics to RF engineering. Wave interference indeed
can cause a redistribution in the direction of energy flow. Wave
cancellation doesn't just happen one time and it's over. Wave
cancellation is a continuous steady-state process and continues
until the source is shut down. It appears to me that is what you may
be missing.

Nowhere in Brown, Lewis and Epstein's IRE paper titled "Ground Systems as a Factor in Antenna Efficiency" is there ANY documentation of the actual ground conductivity that was measured, or even calculated for the antenna site and/or the propagation path used. It was unimportant for the construct and relevancy of the tests and conclusions which the paper reported.

This is the paper I was referring to in my previous posts.

Hi Frank

Yes the usage of the 1/4 wave section is simple and well known. I have
been doing it for years. The loop Z varies somewhat depending on shape
and height over ground. I am modelling a triangle and it runs around 145r

When I create the "wire" in free space by istelf I get a warning;
Error: Wire 5, seg 91, Ex-src: Not allowed near open wire-end

Mind you it comes up with seemingly the correct result. If I change the
number of segments in that wire from 1 to 3 the error doesnt occur.

More feeling my way at this...

What I'd really like to do is setup a dual band single quad loop (ie one
loop inside the other) for (say) 20 and 40M with no ATU. ie direct coax
feed...

Cheers Bob

Roy, I don't have the Wait and Pope paper for review, but I'm
concerned over the validity of their equations that you say render
BL&E's measurements invalid. How can their measurements be invalid
when field-strength measurements of literally thousands of AM BC
antennas agree with BL&E's? Keep in mind that every BC station that
uses a directional array is required to prove the performance of the
array with field strength measurements that assure the measured values
agree with the calculated values.

It was only after verifying BL&E's measurements by comparing their
data with those obtained from many subsequent measurements of BC
antennas that the FCC used the BL&E data in standardizing the
requirements for radial systems for new BC stations.

Isn't it possible that Wait and Pope's equations relate to some other
aspects of BC antennas than those of BL&E? I simply cannot accept the
notion that BL&E's data is wrong.

I think if one knows he code is a true amateur radio operator. One never knows when the code will come in handy. Although, I must admit I am very lax on using it. I haven't used it for years, but I am trying to brush to on it. I find it fascinating.

Ok Bob, now I understand what you are doing. I am familiar with using a quarter wave stub for matching. What I did not understand is the type of error message you were getting.

I use a different version of NEC 2 (Nittany Scientifics' NEC-Win Pro). It does not return an error message when attempting to use a single segment wire, with a source, to feed a transmission line model. I don't think you need worry about the message, since NEC will return the correct solution. You can always experiment with the "TL" card by placing a known load at one end, and observing the input impedance to see that you get the expected value.

I have attempted modeling a double extended zepp, with a source at one end, and the results are completely wrong so guess the error message is required to cover such events. Constructing a physical transmission line model overcomes the double extended zepp problem.

Typical NEC code dealing with the "TL", as per L.B. Cebik, in his book "Basic Antenna Modeling, a Hands on Tutorial" is as follows":

```
.
.
GW 1 21 -3.418 0 15 3.418 0 15 0.000814
GW 2 1 -0.1 0 5 0.1 0 5 0.000814
.
.
TL 1 11 2 1 75 15 0 0 0 0
.
.
```

I'll add to that.

True amateur radio operators can build spark gap receivers and
transmitters from scratch using materials they have in their junk boxes.

Hi Gary,

You don't need precision, so building your own is a good option. The
circuit would be a switched, cascaded pi-network of resistors also
known as a decade attenuator.

You need only three resistors and a DPDT switch for each section. The
traditional sections add 1, 2, 2, 5, 10, 20, 20, 50 dB of attenuation.
For RDF you can skip the first 3 or 4 sections.

Not correct. What you don't seem to grasp here is that's exactly the same as saying 'a standing wave pattern causes energy to be redistributed'. Wave interference is simply the visible manifestation of a redistribution of energy. It is a result. It is not the cause of the redistribution.

What you need is a standard Piston attenuator whose performance is
largely calculable. Forget about dinky wire-ended resistors whose
performance in attenuators is a matter of guesswork.

Reg.

Gary & JG & YD-

If the Buddipole is the one I'm thinking of, you can make out a lot
cheaper by buying or making a bracket that has capability of mounting two
mobile whips as a dipole.

I have one that came from the Lakeview Company in Anderson, South
Carolina. I have it mounted on a five foot section of TV mast supported by
a roof-mount tripod from Radio Shack. I've seen slightly different
brackets from other companies at hamfests.

I tried it with a pair of different mobile whips. One was a single-band
Ham Stick (Lakeview?) and the other a Hustler. On 40 Meters it didn't
work nearly as well as a full dipole, but not bad for an indoor loaded
dipole about five feet off the floor!

One of the problems, if you want to use the attenuator to get close to a strong transmitter, is that typical ham receivers aren't shielded all that well, and you'll find that the attenuator is unable to give you as much signal attenuation as you'd like. (Disconnect the antenna from the receiver entirely, and the signal's still strong!) A way around that is to build a mixer in a well shielded box, mixing the signal with some fairly low frequency to offset it from the transmitted frequency. You listen on the mixer output freq. For example, if you mix with 10MHz, you'd listen to 455MHz at 465 (or 445). Then you have a knob to control the efficiency of the mixer in some way, and you get an output that can be attenuated smoothly. We used to use such things here, and they seemed to work well for the small effort involved in putting them together. I don't think I still have a schematic around, though.

If you build a step attenuator, be aware that at 500MHz, it's tough to keep signals from leaking around your attenuator stages. Be sure to keep leads extremely short. Use switches with low inductance...tiny DPDT slide switches can be pretty good. And don't try to do more than about 20dB in any one stage. Unless you have an exceptional receiver, you'll probably find that you can't use more than about 80dB total attenuation effectively, if that much.

Another useful tool if you're looking for a nearby well-hidden transmitter is a field strength meter. It's possible to build one with logarithmic response, so you can see 60dB or more range easily on a meter scale. Some of the Analog Devices, or Linear Technology, or National Semiconductor dB-linear RF detectors should work well. You can detect inputs below a millivolt with them. Add a tuned circuit on the RF input to keep other signals out. If you build the FSM so it's well shielded and you can swap between say a quarter-wave whip and a tiny stub for antenna, you can cover quite a range of field strengths.

Too bad you're not closer...I'd give you my old doppler RDF. But you have some very good RDF teams in Australia, I know, and maybe some of them could help you out with ideas and construction help if you need it.

Cheers,
Tom

Rest easy, Walt. To my knowledge, no one has ever shown BL&E's *measurements* to be invalid, or the conclusions reached from those measurements. It's their mathematical treatment of what they expected to happen, in the first part of their paper (Part II: Theoretical Considerations), that wasn't correct. I don't believe I have a paper that details the errors they made, but it was regarded my later authors as being in error, prompting a great deal of more rigorous work. Later authors don't generally even reference that BL&E theoretical mathematical work. Nearly all reference their measurements, however, as they should.

There you go again, playing semantic games, and trying to force
your pet definition of "cause" on the rest of the world. You
have obviously tried to redefined cause to mean "first cause",
a concept that has so many holes in it that you can use it for
a sieve.

By saying the above, you are disagreeing with the following web page:
http://micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index
.html

> What you don't seem to grasp here is that's exactly the
> same as saying 'a standing wave pattern causes energy to be
> redistributed'.

The existence of standing wave indeed does cause energy to be
redistributed. Where the standing wave voltage is zero, the net
energy is redistributed into the H-field. Where the standing wave
current is zero, the net energy is redistributed into the E-field.
It is all because of the standing wave. If the standing wave didn't
exist, that wouldn't happen. Therefore, standing waves cause
energy to be redistributed. A causes B. B causes C. C causes D.
Of course, the standing waves are only one item in a cause and effect
chain. The standing waves are an effect caused by interference between
forward-traveling waves and rearward-traveling waves. The forward-traveling
wave is an effect caused by a source. The rearward-traveling wave is an
effect caused by a mismatched load. The source and the load are caused by
human beings. The load is caused by human choice. Humans beings are caused
by ... See where your "first cause" concept leads? i.e. nowhere!

Following your above logic, I assume you would say the Big Bang
is the cause of everything and nothing since then has been the
cause of anything.

> Wave interference is simply the visible manifestation
> of a redistribution of energy. It is a result. It is not the cause of
> the redistribution.

Wave cancellation is permanent and is first an effect and then a
cause in a long line of cause and effect events. I see now why

your argument cannot tolerate the concept of a before and after.

The two signals coming from two different directions incident upon
an impedance discontinuity cause reflections. Wave cancellation is
caused by permanent destructive interference between two of those
reflected waves. The Wave cancellation in turn causes the energy to
be redistributed. Let's parse the following so even you can understand it:

"All of the photon energy present in these waves must
somehow be recovered or redistributed in a new direction,
according to the law of energy conservation ..."

Wave cancellation causes an energy redistribution. This is obvious
to anyone except someone who believes the Big Bang was the only
cause ever. You remind me of the bully who beats up his wife and
then says, "She caused me give her that black eye."

Here's your logic once again. Lightning hits my ICOM and fries it.
Was lightning the cause? No. Was a low pressure depression the
cause? No. Was whatever caused the low pressure depression the
cause? No. There must have been something before that. Maybe the
proverbial butterfly flapping its wings in China? See how
silly your argument is?

>
>This is the paper I was referring to in my previous posts.

Hi OM,

Both Reg and you would do well to obtain and read a copy.

On page 757 is introduced the necessary discussion of:
Is = Iw + Ie
"The we will denote the total earth current flowing radially inward
... as Is, ... where Iw is the component flowing in the wires, and Ie
is the part which actually flows in the earth.

The discussion of earth conductivity (quite specifically named as
such) within the paper spans pages 757, 758, 759, 760, with numerous
citations and graphings against specific conductivity values applied
to related figures in page 761, 762, 763, and 764.

On page 758:
"The actual earth current and the current flowing in the radial wires
are given by..." introducing formula (8).
Followed on page 759 with:
"while the current actually flowing in the earth is...." introducing
formula (10).
"Thus from (8), (9), and (10), together with Fig. 4. we may obtain the
actual current in the earth...."

As for explicit conductivity:
"Fig. 5 shows the current in the wires for the following conditions
... 0.2X10^-4 mhos per cm cube"
"Fig. 6 shows the actual current in the earth for the same
conditions."

"shown for the following conditions..." and four specifications of
conductivity follow.

Now, specifically to a comment I offered as to the importance of
noting conductivity:
"When the earth is of good conductivity, the current leaves the wires
and enters the earth closer to the antenna than does when the earth is

a poor conductor."

There is also a formulation for Fig. 17 (page 766) that is introduced as "The current is flowing toward the antenna through a ring of earth of radius..." which computes the power lost to ground for a known conductivity (with examples abounding).

In this short span of 8 pages dedicated to earth conductivity there at least 12 graphs and charts all quite distinctly displaying the variation of measured results as a function of different specified ground conductivities antennas and ground system combinations.

The authors were quite aware of the ground beneath their feet and duly reported its contributions in the standard engineering fashion of displaying first principles.

Yes, they were purchased by a grocery chain and have pretty much
abandonded amateur radio products, focussing more on consumer
electronics with electronic components available in the larger stores
(for the moment).

They also own Tandy in Oz, so Tandy stocks are near identical to Dick
Smith (less the electronic components).

> Not correct.

Note I said "can cause", not "will cause".

Jim, you caused me to hit the books on cause and effect and
the effect was a refresher course on what I already knew.

From "Introduction to Logic", by Copi: "The word 'cause' is
sometimes used in the sense of necessary condition and
sometimes in the sense of sufficient condition."

Is permanent wave cancellation a sufficient condition
for a redistribution of energy to happen. The answer is "yes"
according to my web page references. Therefore, permanent wave
cancellation *will* indeed cause a redistribution of energy.

Please note above that I said wave interference indeed *can*
cause a redistribution of energy. I chose "can" instead of
"will" because wave interference is not sufficient to cause
the redistribution of energy. Wave cancellation is a special
case of wave interference in which the waves *cease to exist*
in their original direction of travel. The conservation of
energy principle dictates that the energy contained in those
waves before they are canceled, must necessarily be redistributed
along a different path. Note: Any different path in a transmission
line is necessarily the opposite direction, i.e. a reflection.

Jim, try the following on for size:

Let us now determine why open or short circuits are developed by wave interference. From King,37 we know that voltage and current traveling along the line can be represented by individual generators placed at any point along the line. Those generators are called "point generators." For the purpose of analysis, a point generator is an impedance-less EMF that can represent or replace the voltage and current on the line equal to the voltage and current actually appearing at that point on the line, without disturbing the wave action on the line.
To simulate and analyze interference between two waves of equal magnitude and opposite phase traveling in the same direction, such as the two sets of reflected waves generated by the load mismatch and the stub mismatch, we can connect two point generators together in either of two different configurations. Each generator replaces the voltage and current of each individual wave at the point of interference, the match point. In the first configuration, the two generators are connected in phase. Because their voltages are equal and in phase, the differential voltage is zero, resulting in no current flow. This connection is equivalent to an open circuit between the generators. In the second configuration, the generators are connected with their terminals reversed. Their voltages are now in opposite phase at the interference point and the resulting voltage is the sum of the voltages delivered by each generator; i.e., twice the voltage of each generator. This connection results in a short circuit between the two generators.
Identical wave-interference phenomena establishing a short circuit also occur in free space in the same manner as in guided-wave propagation along transmission lines. For example, when the fields emanating from two radiators in an array of antennas are of equal magnitude and 180ï¿½ out of phase at a point in space, a virtual short circuit is established by destructive wave interference, resulting in a null in the radiation pattern at that point. Following Poynting's Theorem, the energy in the combined fields propagating is reversed in direction at that point; and with the constructive interference that follows, that energy adds to that in the fields propagating in the opposite direction, thus achieving gain in the that direction.

Until now I have not contributed to this discussion. Neither now and very little in the past. So please leave me out of it.

I have produced one small program (I am surprised at the attention drawn to it) which computes radiating efficiency of a short vertical antenna based on a novel analysis of ground loss, ie., shallow buried radial wires which behave as lossy transmission lines.

All I have to say is that the program gives the "right" answers. Disprove it if you can.

It is as accurate as the ground "constants" are known, that is about plus or minus 30 percent. The answers are forthcoming within milli-seconds. No need to go on a one month training course. And it's free. What more do you want?

To prove it wrong you have to create a set up similar to that pruduced by BL&E - only this time don't forget to measure ground coductivity and permittivity!

From what Roy says, BL&E were hardly better than bungling amateurs of their era. The only reason their report is considered to be 'The Bible' is because it was the only one ever produced and available at the time.

They laid down so many radials it didn't matter what ground conductivity was.

Generally, when people build these, they put a shield down the middle of
each switch. Note that one of the resistors of each section and the bypass
strap have to pass through holes in the shield.

All correct - neither proving your point or disputing mine.

The thing you really need to consider is: how much energy is actually
"in" a wave (whatever that means) that delivers no energy.

Hi Walt,

I think that is all well and good, Walt - except for your statement regarding the Poynting theorem. I can find no support in the literature for a claim that interference changes the direction of the Poynting vector - or for that matter, is a cause for any other phenomenon to occur. I once asked you for a reference, but your books weren't handy at the time. Let me know if it turns up. I am very interested to take a look at it.

Thanks,

Jim Kelley

I have the paper, and have read it carefully, many times. The paper gives equations and graphs for current in the radial wires for a perfectly conducting Earth, and for Earth conductivities of 20 x 10^-15 e.m.u. and 100 x 10^-15 e.m.u. Later, in the experimental data, they report measurements of the currents for various radial configurations during their measurement sequences. But as I wrote, nowhere do they specifically report the actual ground conductivity for the antenna site, or along the 0.3 mile propagation path of the test. If you can find that anywhere in that paper, I will promptly retract my statement, and apologize.

Figure 30 in the paper shows that the ground system comprised of 113 radials of 0.412 lambda each resulted in a measured field strength that was about 0.18 dB below the theoretical value for it from a 90 degree radiator against a zero-ohm connection to a perfect Earth. I expect most of us would be quite happy if our measured data agreed that closely with its theoretical value. In any case it does show that the actual value of the ground conductivities for the test site and path had a trivial bearing on the test results, e.g., it was unimportant.

In fact the efficiency of AM broadcast vertical radiators per the FCC definition always is based on a perfect ground plane, and two ohms or less of DC resistance in the transmitter connection to it (via the radial ground system). Only then is distant field strength determined, using the radiator efficiency value and applied RF power along with the appropriate FCC propagation curve for the frequency and Earth conductivity for the path.

Well, Jim, did you really grasp the paragraph above? How do you
suppose that had it not been for wave interferencethe energy would
have continued on in a particular radial direction, but due to the
interference the result was a null in that direction and an increased
amount of energy in the opposite, or forward direction, achieving gain
in that direction? The energy certainly changed direction to achieve
this condition. And you don't need references to understand this
phenomenon either. There are some concepts that are understandable
intuitively.

Please Jim, don't tell us that the energy isn't changing direction in
the rearrangement of the power distribution in the antenna pattern
that is wholly caused by wave interference and nothing else.

Walt

Hi Walt,

What stopped it if not a physical barrier?

>but due to the
>interference the result was a null

A null is not the absence of energy, but is the combination of equal
and opposing forces. If you were the Ref at a title bout, and stepped
between two punches of equal magnitude; then you wouldn't move very
far, the motions would cancel, but most would doubt you'd be up again
before the "count."

Nulls are evidenced quite clearly in bridges of many designs. They
may balance between huge potentials (energy), but evidence absolutely
no current (or power from energy times current). If you unplugged the
equipment from a bridge, the absence of current would not be an
indication of a null. Nulls within the context of engineering
necessarily carries the implication of energy present.

>in that direction and an increased
>amount of energy in the opposite, or forward direction, achieving gain
>in that direction?

Linear systems do not exhibit "gain." The combination of forces are
due to the total field in comparison to the region of interest.

It is by similar simplifications that we have contributors here who
offer that the radials of elevated ground planes do not radiate
energy. Their contribution to producing a power at a remote load may
cancel such that no power is evident, but this does not negate the
radiation nor the energy present.

Hi OM,

As stated previously:

"Fig. 6 shows the actual current in the earth for the same conditions"

I hope the word "actual" is not subject to recourse to the IEEE
dictionary for clarification.

The "same conditions" are explicitly specified with conductivity.

One has to trust that engineers did not ask the farmer's wife to make
this determination for them in her kitchen. The imputation of
distrust would seem to serve another agenda.

Figures 7, 8, 9, and 10 also are all quite explicit.

The paper offers enough data to render your objections as tedious as
my work disproving "total cancellation" - the difference being I did
the work instead of simply saying "'t'ain't so." ;-)

> The "same conditions" are explicitly specified with conductivity. etc

---

Yes, BL&E reported on the currents in the radials and the total ground currents during the test (as I already stated), but that is not the issue. The issue is whether or not not they explicity reported the value of Earth conductivity for the test site and propagation path--and they did not. Nor was it important to the conclusions of the test.

4081. What's a piston attenuator? (was Variable Attenuator)

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-09 21:48:00 UTC
From: SignalFerret <signalferret@verizon.net>
Message-ID: <kw9Ke.6801$0d.2865@trnddc02>
Source record: 71999

Just curious, what is a piston attenuator? For the life of me I can't seem to picture it. I know how a slab of resistive material inserted in to a wave guide works as an attenuator, but how is it accomplished in a coax transmission line? If someone has a photo, or diagram of the inner workings that would be great!

> dictionary for clarification.

I agree with Richard Fry. All the references to ground conductivity, including Figure 6, are in Part II, the (erroneous) theoretical treatment. As for the "actual", look back a page, to page 759, at the bottom, where they say, "Thus from [equations] (8), (9), and (10), together with Fig. 4 ["Calculated Values of Total Earth Current"], we may obtain the actual current in the earth and the current in the wires." So the "actual" current is calculated from three equations and a graph of calculated current. Whatever they might have meant by "actual", it doesn't mean that it was measured.

They are also part of the theoretical treatment and don't represent measured values. Measured values begin with Fig. 25.

> . . .

Brown, Lewis, and Epstein did a good and careful job of measurement. Please be careful not to confuse their not-so-good theoretical treatment with their measurement results.

Considering that Brown, Lewis, and Epstein's experimental work has held as being valid for about 70 years now, it can be used as a test for various attempts at calculating ground system losses. NEC-4 matches their results quite well; your program produces results which are dismally different. Anyone armed with both the BL&E paper and your program can see for himself.

> It is as accurate as the ground "constants" are known, that is about
> plus or minus 30 percent. The answers are forthcoming within
> milli-seconds. No need to go on a one month training course. And it's
> free. What more do you want?

It's sure a lot easier to create an easy-to-use free program if the results don't have to bear any resemblance to reality. But perhaps you're right -- maybe people who use free software shouldn't expect the author to be honest about the program's accuracy.

> To prove it wrong you have to create a set up similar to that pruduced
> by BL&E - only this time don't forget to measure ground coductivity
> and permittivity!

Your program fails badly with any reasonable ground conductivity and permittivity. NEC-4 does pretty well with reasonable assumptions for the ground quality of a field in New Jersey in the wintertime.

> From what Roy says, BL&E were hardly better than bungling amateurs of
> their era.

Once again, you've crossed the line from your normal pomposity and crankiness to an insult and lie.

The only reason their report is considered to be 'The
> Bible' is because it was the only one ever produced and available at
> the time.

Another untruth. It stands because their measurements took in quite a number of conditions, and have been replicated.

> They laid down so many radials it didn't matter what ground
> conductivity was.

Those people who have read the paper know this to be untrue, also. They made measurements with 2, 15, 30, 60, and 113 radials.

Isn't that kind of a record, Reg, three flatly untrue statements in a single posting? You should record the name of that wine and save it for those special occasions when you feel threatened by the possibility that some Yanks might have done something useful 70 years ago. Hope your favorite store has lots in stock. In vino veritas, indeed.

Resistive material is not involved. The piston attenuator works by
varying the length of an empty metal tube, down which the signal has to
propagate as an EM wave. The tube is a waveguide operating below its
cutoff frequency, so the attenuation depends on the length and can be
calculated from first principles.

Attenuators using small wire-ended resistors would certainly be good
enough for this particular application, where accurate attenuation
values are not required. The performance of such attenuators has often
been measured, so it's far from being guesswork. If they are well
constructed, with attention to short leads, layout and shielding, they
can be quite accurate up to about 400-500MHz. However, that still
leaves the problem of poorly shielded rigs, which allow RF to leak
straight in past the attenuator.

A simple way to de-sensitize a handheld rig for close-in RDF purposes is
to lower the whole rig (antenna and all) into a metal pipe, on the end
of a piece of string. The further you lower the rig inside the pipe, the
less sensitive it becomes. It may look crude, but this is Reg's piston
attenuator in action!

This system has no directional properties, but at short range you can
often "DF" on signal strength alone.

Hi Robert,

It is a "below wavelength cutoff attenuator." It is basically two coupling loops put in a conductive tube the size of a toilet paper roll. One loop is movable on the so-called "piston" (although the resemblance ends there, no compression is expected). At the other end of the "cylinder" is the other loop. As you draw away, or closer, the attenuation is linearly variable to quite a high degree.

Of course, all other provisos still apply.

There are far more step attenuators than these, however amateurs like doing simple things difficultly. If sealing the box of the stepped attenuator was difficult, I can imagine the fun of circular seals. Nothing precise nor accurate is required for RDF - but low leakage does win at the end of the day.

I keep telling you that our only technical disagreements are over
extremely minor points. You keep posting stuff as if we disagree
when we don't and it is mostly just a ruse. You keep trying to
forcefully shove your strawmen into my head so you can shoot them
down, but that is just another ruse.

It appears to me that you think wave cancellation is a one time event,
like shooting a deer. The deer dies and that's that. But wave cancellation
is not a one time event. Wave cancellation is a continuous steady-state
infinite series of infinitessimal events. Wave cancellation is not possible
without steady-state standing waves. If the forward power anywhere in the
system is greater than the source power, then wave cancellation and
constructive interference are continuously occuring during steady-state.

> The thing you really need to consider is: how much energy is actually
> "in" a wave (whatever that means) that delivers no energy.

"In" in this context means "associated with" (and two letters is
seven times as efficient as 14 letters). Energy is always associated
with any wave, else the wave would never exist. For you to talk
about canceled waves containing no energy is a contradiction. Dr.
Best talked about canceled waves that keep flowing toward the source,
canceling each other all the way, but containing zero energy. They
exist only in his mind.

All waves deliver energy somewhere even if it takes forever as in the
case of the detected background radiation. In a lossless transmission
line, all waves deliver energy to the load (and possibly to the source

after power to the source is removed). Rearward-traveling canceled waves deliver their energy components in the direction of the load to later become incident upon the load. Anything else would violate the conservation of energy principle. The path the canceled waves take can be deduced by observing ghosts on a TV screen.

There is no such thing in reality as a wave that delivers no energy. Waves cannot even exist without energy. Canceled waves have associated energy components before they were canceled. The Melles-Griot web page calls that energy the "lost" energy and says it is not lost at all. Those energy components must be redistributed in different directions after the waves are canceled. Redistribution of energy in a transmission line means changing direction, since there are only two directions.

A very simple form of a piston attenuator for the OP's application is nothing more than a metallic tube into which you can suspend the receiver on a string. Adjust how far you drop the receiver into the tube (held vertically) to adjust the attenuation. Seriously. You can wrap a cardboard tube about three or four inches diameter with aluminum foil to make the "meatllic tube." It's a trick that many locals here have used effectively in hunting hidden transmitters.

A more usual form is a tube with a couple of coils in it, with a means to adjust the separation of the coils. See the third paragraph of
http://www.measurement.gov.au/index.cfm?event=object.showContent&objectID=816180ED-BCD6-81AC-1B55FA54D509991D#attenuators
for an example.
http://ej.iop.org/links/q55/Y67w5gpiNzZ0e8q9qahFCg/jev17i12p1172.pdf is an article about correction of small errors in (precison) piston attenuators. This pdf has a cross-sectional diagram in it, but don't get bogged down in the details.

Cheers,
Tom

The Melles-Groit web page certainly supports wave cancellation being the cause of the "lost" reflected energy joining the forward wave. The Molecular Expressions web page certainly supports that same energy redistribution resulting from wave cancellation.

And given the following example from "Fields & Waves ..." by Ramo & Whinnery, what do you think changes the direction of the Pz2- Poynting Vector such that it vectorally adds to the Pz1+ Poynting Vector resulting in the Pz2+ Poynting Vector?

100W XMTR---50 ohm line---+---291.4 ohm line---1698.5 ohm load
Pz1+ = 100W--> Pz2+ = 200W-->
<--Pz1- = 0W <--Pz2- = 100W

If you can answer that simple question to the satisfaction of everyone, the discussion will be over.

Any reflections (and Poynting vector reversals) would be caused by the presence of impedance discontinuities - not by anything else. In the absence of impedance discontinuities, the transmission line would appear to be infinitely long and would not produce reflections.

So your claim is that energy is delivered by two waves that are equal in
amplitude and opposite in phase?

> There is no such thing in reality as a wave that delivers no energy.

See Born and Wolf for examples.

> Waves cannot even exist without energy.

Correction. Waves cannot be created without energy. Electromagnetic
fields can indeed exist without necessarily conveying energy from one
place to another.

leads to amusing circularity which I will set aside.

One might well suppose that through fine parsing, "actual" is not, and
is code for "might be." All reasonably argued, but reason has been
replaced with the rhetoric of argument fighting for air.

The authors express that with their formulas (8), (9) and (10) that
results would be "accurate" which I presume parses here to "best
guess." I also note that what falls within the "theoretical"
discussion is couched with the variables set in the "measurement"
discussion. The paper, as would be expected, was written iteratively
and results were drawn back into the theory.

The theoretical discussion of radial counts does not proceed from a
natural 15, 30, 60, 113 progression - this is plainly ad hoc
determination. Nor does the theoretical discussion of antenna height
proceed naturally through 22, 44, 66, 88, and 99 degrees - again
arrived at by ad hoc methods. All such "theoretical" considerations
are the happenstance of what was available in the field. It is
overwhelmingly obvious that Figures 4 through 14 are derived from the
3MHz tests employing antenna sections of 20', 20', 20', 20', and 10'
which fall right on the curve at the 1.098 degrees per foot of section

used. The text clearly states this: "The antenna heights given here were chosen to conform to later experimental heights." This admission precedes the introduction of ground conductivity, and yet after all of this ad hoc conscription from the field flows the presumption that the ground conductivity is derived. To put it bluntly, the data and system variables inhabit the theoretical discussion like a glove.

Like a political promise, the embraced vague genesis of ground conductivity has been heralded for every purpose but what the authors put it to.

I've as often seen the shields between attenuator sections, instead of in the middle of a section. I can assure you, there is plenty of coupling across the switch itself where you can't place a shield, and the coupling is both inductive and capacitive. Maybe use two separate SPDT switches with a shield between them and mechanically ganged?

It's instructive to take apart a good microwave relay to see how they manage high isolation and constant impedance, but check the price of such relays before you destroy one to just have a look at it. (e.g., Digikey 255-1579) With such relays, SMT resistors and careful board layout, you can make a very decent step attenuator up through UHF at least.

Cheers,
Tom

The impedance discontinuity is certainly in the cause and effect *chain*
as is the Poynting vector reversal. But simply asserting that the
impedance discontinuity causes the Poynting vector reversal is
a sophmoric begging of the question and leaves out some important
details. A causes B. B causes C. C causes D. You are certainly logically
correct in saying that A causes D, but your statement leaves out some
important intermediate details, namely B and C. (see below)

For instance, the impedance discontinuity causes nothing unless the
source energy exists and is taken into account as a cause. The
question is what are the necessary and sufficient conditions for an
impedance discontinuity to result in a complete reversal of the
(Pz2-) Poynting vector? Since a source is necessary, the source can
be considered as a cause. (The creator of our species can even be
considered as a necessary cause as can the Big Bang.)

Looking at it from a scientific standpoint, the impedance discontinuity
can only directly reverse half the magnitude of the Poynting Vector because
the physical power reflection coefficient is 0.5. So how does the other half
of the magnitude of the Poynting Vector get reversed? It's all been covered
by the Melles-Griot web page and the Molecular Expressions FSU web page.

In the presence of EM source energy, the impedance discontinuity causes
reflections. One of those reflections reverses half the magnitude of the
(Pz2-) Pointing Vector. That magnitude is (Pz2-)(rho^2).

Two of those reflections engage in wave cancellation. One is (Pz1+)(rho^2).
The other is (Pz2-)(1-rho^2), the other half of the (Pz2-) Poynting Vector.

These two reflections have equal magnitudes and opposite phases and therefore cancel. Their energy components reverse direction and head back toward the load as explained on the Melles-Groit and Molecular Expressions web pages.

And that's how the (Pz2-) Poynting Vector gets reversed. It's a two-step process, each step involving half of Pz2- in the above example.

> In the
> absence of impedance discontinuities, the transmission line would appear
> to be infinitely long and would not produce reflections.

That's true. The impedance discontinuity causes the reflections that engage in wave cancellation. In steps, it goes like this.

A. Impedance discontinuity driven by a source of EM energy

B. Reflections (implied mismatch)

C. Wave Cancellation (permanent destructive interference)

D. Energy direction and momentum reversal (constructive interference)

A causes B. B causes C. C causes D. This is in any freshman logic book. You are certainly logically correct in saying that A causes D, but your statement leaves out some important intermediate details. Those intermediate details are what this discussion is all about.

Gary:

Building is an option, but you can also find some nice commercial units
on eBay which may have simply failed a calibration check. There are
several brands of attenuators out there retired from shops and labs
regularly.

I purchased a few HP 355D VHF attenuators, which are 0 - 120 dB step
attenuators made for 50-ohms from 0 to 1000MHz with a rotary switch.
A couple were just out of calibration (not a problem for my application),
and the cheaper one had some problems with individual steps that could be
repairable. I think I've paid $40 to $90 each for these last year.

The cheapest I found were Kay Electronics 0 - 100 dB attenuators with
nine sections switched by toggle switches. A couple on eBay are about to
sell for less than $20 as I type this!

>and laid 120 radials regardless of economics.

Hi Reg,

For a million dollar station investment, I don't think the price for
shares in Anaconda have brought any significant attention to anyone.

Perhaps you are thinking of the relative price in 1906 when it cost 4
times as much against 5% of what we consume now. Well, maybe only 30
years ago when it cost more than 3 times as much as now. Or perhaps
only 10 years ago when it cost twice as much as now.

Odd, it seems the price of copper and the value of the Pound have been
tracking each other over that same period. Your complaint would be
better founded on us planting sterling radials.

Sorry, as so often happens I missed your point entirely. If you're interested in having me understand what "circularity" you mean, you'll have to be more blunt and pedestrian so I'm able to understand it.

>
> One might well suppose that through fine parsing, "actual" is not, and

Again, I haven't a clue what you're talking about. Arguing semantics, I suppose, in which I'm afraid I have no interest.

> The authors express that with their formulas (8), (9) and (10) that

> and results were drawn back into the theory.

I'm missing this one, too. If you're saying that those three graphs are of measured data, I can present what I believe is a good argument against that premise. But I can't tell if that's what you're saying or not.

> The theoretical discussion of radial counts does not proceed from a

> proceed naturally through 22, 44, 66, 88, and 99 degrees - again
> arrived at by ad hoc methods. All such "theoretical" considerations
> are the happenstance of what was available in the field.

It wouldn't surprise me a bit if the theoretical work was written or modified after the measurements were made, which I believe is what you're saying. That doesn't alter the fact that the graphs of Part II are from calculated rather than measured results.

> It is
> overwhelmingly obvious that Figures 4 through 14 are derived from the
> 3MHz tests employing antenna sections of 20', 20', 20', 20', and 10'
> which fall right on the curve at the 1.098 degrees per foot of section
> used.

I'm not sure what you mean by "derived from", but they sure aren't graphs of measured data. For starters, some of those graphs are for 1 MHz, while according to the paper all measurements were made at 3. For another thing, I'm sure they didn't have the ability to change the ground conductivity; some of the graphs are for different ground conductivities than others. Finally, compare Figures 7 and 8 with Figure 42. The latter is from measured results, as explained on p. 781. It's quite different from the theoretical results for Figures 7 and 8. Incidentally, the theoretical analysis, including Figures 7 and 8, seems to assume infinite radial length, which is another difference between the theoretical and measured conditions (besides ground conductivity and, in some cases, frequency).

> The text clearly states this: "The antenna heights given here
> were chosen to conform to later experimental heights."

That's a very reasonable thing to do, when presenting both theoretical and measured results. I believe you're drawing conclusions from it which are well beyond its straightforward intent. (Perhaps this is due to your English literature background? It certainly was one of the activities overwhelmingly emphasized and encouraged in all English lit courses I ever took.)

This admission
> precedes the introduction of ground conductivity, and yet after all of

Jim Kelley wrote:
> So your claim is that energy is delivered by two waves that are equal in
> amplitude and opposite in phase?

Naturally, zero energy is delivered in the direction of the complete
wave cancellation. The energy in the two canceled waves is delivered
in the opposite direction from their power-flow vectors. Anything else
would violate the conservation of energy principle.

It's not really my claim. That is what is claimed by the Melles-Groit
and Molecular Expressions web pages. That is what is claimed by Hecht,
in "Optics". That is what is claimed by Walter Maxwell in "Reflections".
Walt calls it a "virtual short". I had forgotten that he had described
it so well until I re-read it. Walt's QST articles in the 70's were where
I encountered these principles for the first time.

Maxwell, Walter, Reflections II, ï¿½ 2001 Worldradio Books

Page 4-3, "The destructive wave interference between these two complementary
waves ... causes a complete cancellation of energy flow in the direction toward
the generator. Conversely, the constructive wave interference produces an energy
maximum in the direction toward the load, ..."

(I had forgotten about that being in "Reflections". "Optics" was only
a refresher of the "Reflections" material.)

Page 23-9, "Consequently, all corresponding voltage and current phasors are 180
deg out of phase at the matching point. ... With equal magnitudes and opposite
phase at the same point (point A, the matching point), the sum of the two
(reflected) waves is zero."

>> Waves cannot even exist without energy.
>
> Correction. Waves cannot be created without energy. Electromagnetic
> fields can indeed exist without necessarily conveying energy from one
> place to another.

Correction. DC electromagnetic fields can exist without conveying energy
but the context is RF EM waves. EM wave-fields cannot exist without energy.
They can only exist at the speed of light, i.e. with ExM joules/sec
passing a point. The use of your tricky-dicky definition for "convey"
doesn't change those facts of physics.

Except that D is not caused by, and cannot be caused by C. Only
reflection can cause reflection. The claim that momentum reverses
direction without encountering a physical reflector is a violation of
conservation of momentum.

In a title bout two punches of equal magniude are coming from opposite
directions. The energies in the two punches is dissipated in the
noggins of the morons who got into the bout;. The resulting null is in
reducing the already worped brains to zero.

>Nulls are evidenced quite clearly in bridges of many designs. They

We're not talking about nulls in bridges, we're talking about energy
controlled in desired directions, reduced in some directions, with the
energy lost in one direction adding to that in another; but you know
this.
>>in that direction and an increased
>>amount of energy in the opposite, or forward direction, achieving gain

Well, Richard, there is no non-linearity in the formation of antenna
radiation patterns. Are you saying there is no 'gain' when energy is
taken from one direction and pushed into another? With respect to
radiation patterns, 'gain' is relative, and not consideredas an

increase in power. But you know that too.

>It is by similar simplifications that we have contributors here who

My comments are totally unrelated to elevated ground planes. I'm only trying to prove to Jim that wave interference DOES cause energy to shift direction without any aid of a physical entity. The only cause of the change in direction of energy radiated from an array of dipoles is wave interference, the interference between the waves emanting from the different dipoles.

Hi Richard,

You may recall this came up before. The example I noted was in the instance of total internal reflection. Page 47, "Principles of Optics" Born and Wolf. When the angle of incidence with respect to the normal exceeds the critical angle "no light enters the second medium. All the incident light is reflected back into the first medium and we speak of total reflection. Nevertheless the electromagnetic field in the second medium does not disappear, only there is no longer a flow of energy across the boundary." They footnote that an elegant experimental demonstration is described by W. Culshaw and D. S. Jones Proc. Phys. Soc. B 1954.

It's also arguable whether any energy is transferred from a source to a lossless, open circuited, 1/2 wave transmission line after the transient period. Though there's no uncertainty about the presence of electromagnetic waves on such a line in the steady state.

Hi Roy,

You consistently demur expertise in English, and you are equally
troubled in Blunt, but the plea for help cannot go unanswered.

Let's see, we have a premise that the ground conductivity was
concocted from formula for the BL&E paper. If we proceed along the
lines this is true, then we immediately are faced with the conundrum:
>>>ground quality of a field in New Jersey in the wintertime.

How was this determination made? When was this determination made?
What was the determination made? Oh well, all such quantitative
discussion is missing so the statement appears to have as much basis
as a guess, but we are faced with the complaint holding Reggie to a
higher standard:
>>>Your program fails badly with any reasonable ground conductivity and
>>>permittivity.
compared to what determination? Where? of What? by Whom?

This appears to be a war of wills between the best guessing software.

Can we presume the answers lie with:
>>>Brown, Lewis, and Epstein did a good and careful job of measurement.
which, by the leading hypothesis contains no measure of conductivity?

So the objection to Reggie's software not conforming to results
offered by NEC-4 is proven by:
>>>NEC-4 does pretty well with reasonable assumptions for the
>>>ground quality of a field in New Jersey in the wintertime.
a strained appeal through BL&E,
>> NEC-4 matches their results quite well
which, by the leading hypothesis contains no measure of conductivity.
Which from FCC charts would suggest it to be uniformly dismal.

I've seen no discussion of actual quantifiable results against these
claims offered, so there is every chance that they are pinned together
by the evident circularity:

1. There has been no measurement of ground conductivity by BL&E
2. Reggies model for ground conductivity counters NEC-4
3. NEC-4's model for ground conductivity conforms to BL&E

4. There has been no measurement of ground conductivity by BL&E

I would like to see:
>>>Your program fails badly with any reasonable ground conductivity and permittivity.
supported by something other than appeals to dead white engineers -
Reggie has a patent on that method already.

The radiation pattern of an antenna is the result of the superposition of fields either radiated or reflected from REAL surfaces. Energy from the radiating and reflecting elements travels only in directions where the resulting superposed fields are not zero. The resulting interference pattern is simply the plot in 3 dimensional space of where energy is being directed.

You missed the point, Jim. The wave indeed does encounter a
physical reflector and indeed cannot happen without the physical
impedance discontinuity. It meets all of your requirements.

Use a signal generator with a circulator load as the source. Cause a
noise glitch on the source signal. When will you see the glitch
across the circulator resistor? One cycle later. Reckon where that
glitch went during that one cycle? Man, that's a tough question. :-)

Hi Walt,

What is being discussed is energy. Energy is wholly transparent to
application. The laws for its conservation don't care if you are
shooting marbles or colliding stars. Physics eventually devolves to
very few units of measure and the books balance on both sides of the
event.

>>>in that direction and an increased
>>>amount of energy in the opposite, or forward direction, achieving gain

>radiation patterns. Are you saying there is no 'gain' when energy is
>taken from one direction and pushed into another? With respect to
>radiation patterns, 'gain' is relative, and not consideredas an
>increase in power. But you know that too.

And we both know no energy is created or lost without an atom being
ripped apart. The appeal to antenna "gain" is simply the choice of
where your attention is focused. Energy is neither lost nor created,
nor increased, nor decreased, the concomitant power that results of a
load being exposed to several sources of energy has a resultant. That
resultant expressed in the gain charts presumes there is a continuum
of loads throughout the circle/sphere of the lobes being described.

>the different dipoles.

Elevated ground planes, if they do not fit into the discussion, reveal that discussion cannot support their characteristics. This is expressly a failure of that discussion.

Elevated ground planes radiate from the entire structure. What they radiate is energy. The net sum of those energies, at a distance, combined into a load, reveal that the contribution of the radials nullifies in horizontal polarity, and because the relative height (thickness) of the radials is so small in proportion to the main vertical element, make very little contribution to the vertical polarity. Yet and all, every radial element is blasting away in proportion to its current and radiation resistance. The radials are pouring energy into the ï¿½ther with every effort as the main vertical element. Reduce this to the barest minimum of two radials and the results are identical, however, lop off to one radial element, and the energy balance upsets the apple cart and a horizontal component, formerly offset by equal opposing energies, appears. That last radial element had always been radiating energy, it is still radiating energy.

Optics has been maligned through very poor examples here, but if two beams of light intersect we have wave interference ONLY if a load is present at that intersection. A load is a necessarily physical correlative. Otherwise, these energies have absolutely no interaction, barring a non-linear medium.

It then follows that waves do not mix freely in and of themselves and hence they are not causative agents. This has been illustrated by The Extreme Failure of Poor Concepts in Discussing Thin Layer Reflections.

Yup. Pringles cans are often used for this. I made a nice
heavier-duty version by recycling the lower half of a water-filter
cartridge - light aluminum, easily hacksawed to the desired length.

>This system has no directional properties, but at short range you can
>often "DF" on signal strength alone.

You can arrange some amount of crude directionality by holding the
attenuator-tube-with-HT-in-it in front of your torso, right next to
your chest, and then spinning around in place. This "body fade"
technique can give you a reasonably directional null when you're
facing away from the signal source. If the null isn't sharp enough,
lower the HT further into the tube to increase the attenuation, and
try again.

The attenuator that G4PMK published in 'The VHF/UHF DX Book' was based on earlier ARRL publications. It used common low-cost slide switches, and 1% 0.25W metal film resistors mounted directly on the switch tags with the shortest possible lead lengths. There were screens between the switches.

The following is a selection of results (which I didn't have time to type out last night). The 'Theory' column is the attenuation expected from using available resistor values, and the '1MHz' column shows the actual DC/LF result. Then read along each line to see how the attenuation changes with increasing frequency.

Best viewed with a fixed pitch font...

Nominal Theory 1MHz 30MHz 145MHz 432MHz
dB
1 0.98 0.98 0.97 1.00 1.27
3 3.02 2.88 2.81 2.92 3.45
10 10.08 10.06 10.10 10.09 10.56
20 19.9 20.0 20.0 19.9 19.7

That's really pretty good; in fact some of the apparent error may be due to the network analyser that was used for the measurements.

It seems that the main effect is a small *rise* in attenuation with frequency, probably caused by the increasing inductive reactance of the resistors. There doesn't seem to be any problem with internal coupling for these particular switches.

Your mileage will definitely vary. This is partly because of the switch construction, though garden-variety slide switches are all pretty much the same. Another source of variation is that metal-film resistors of the same value coming from different manufacturers may have significantly different values of series inductance. However, very small 1% metal-film resistors are the best wire-ended components you can get for this application. (My article in RadCom a few months ago has more information. Don't even think of using carbon composition!)

>It's instructive to take apart a good microwave relay to see how they

>least.

You certainly can. Part of the solution seems to be to use a physically separate SPDT switch at each end of the attenuator, rather than DPDT type where the switches may be too close together. Some commercial step attenuators use individual switch contacts operated by insulating push-rods, and a long rotating cam-shaft selects the combinations required.

Yet another option is to use complete individual attenuators, shielded from one another inside a rotating 'turret' block.

> 4. There has been no measurement of ground conductivity by BL&E

At least now you admit that BL&E didn't measure ground conductivity. That's progress.

First things first. The goal of BL&E's experimental work was to relate the 'efficiency' of MW vertical radiators of various electrical heights to radial ground systems of various configurations. It did not state or find that ground conductivity had any significant bearing on this, and, as shown by their measured results, it did not.

The entire theoretical section of this paper where ground currents are calculated, and the references to ground currents that were measured during the experimental work could have been omitted both from consideration and measurement without changing the conclusions of the paper. None of that was significant to their measured results for field strength vs system configuration, which was the purpose of their efforts. And omitting it would have spared you your confusion.

The FCC considers every non-sectionalized AM broadcast vertical radiator of a given electrical height using a given radial ground system to have a given efficiency. Period. Ground conductivity at the radiator site has nothing to do with that. It doesn't matter whether that site is in the middle of Kansas with 30 mS/m conductivity, or on Long Island with 0.5 mS/m, radiation emitted from a given antenna+radial ground system will be the same. The purpose of the BL&E field work was to determine those efficiency values, and it did so with high accuracy. Their findings have been a benchmark confirmed at many hundreds (probably thousands) of AM broadcast station applications since 1937.

By the way, even NEC-2 can be used to confirm the results of BL&E's study, by inserting at the bottom of the vertical radiator a low-value DC resistance simulating the resistance of the radial ground system connection with a perfect ground plane. This again shows that ground conductivity is insignificant in determining the radiation 'efficiency' of a MW broadcast vertical and its radial ground system.

Psst... the definition of "polarity" is not same as that of polarization.
Probably you meant to write "polarization," did you not?

Admit it ? You got me wrong!

I was the FIRST to point it out many months ago. I did it politely by
blaming BL&E's poor memory.

Note that my post responded to the comments of Richard Clark,
not to yours.

Now if YOU will admit that there was no reason for BL&E to have measured ground conductivity for this study, and quit saying that they "forgot" to do it--that will be another victory for reality.

It's not really fair to the readers to use a word in an obscure
way and refuse to define it. Since you haven't presented your
esoteric definition for "convey", and it is not in the IEEE
Dictionary, would this be a true statement based on your
definition of "convey"?

The EM light wave energy from the North Star that is absorbed
by a human eye conveyed energy from the North Star to that
human eye. The EM light wave energy from the North Star that
misses earth and continues on through space did not convey any
energy from the North Star.

Those are pretty smart light waves, Jim. How did the ones that
entered the human eye now know many years ago to convey (bring)
some energy from the North Star? How did the ones that miss earth
now know many years ago to avoid conveying (bringing) any energy
from the North Star. :-)

I would guess that a statement like, "These EM waves are in the
process of conveying energy from the source to the load.", sounds
ridiculous to you?

So you say, but what I have written is a relevant commentary on the applicablity of the content and conclusions of the BL&E paper. You have offered nothing to disprove my comments. Nor can you disprove them, because objectively stated reality will not support whatever attempt you might make.

Hi OM,

What you have written is called bloated prose. It is suitable for ad
copy and trade show handouts that tout insignificant advantages only
because there is nothing substantial to present.

Eight pages of discussion from the report covering the conductivity of
earth has been rendered a foot note by your diminution of attention.
Your absurd conclusion that ground conductivity had no bearing on the
outcome is glaring contradiction to the scope and purpose of the
entire enterprise. To reduce this focus of efficiency to copper loss
is a toothpick in the forest of effort by these men.

Not unlike many of the other things you have said in this discourse.

But, take heart. You have brought your evil adversary to his knees.
Your relentless browbeating has finally taken its toll and achieved its
intended purpose. The blaring onslaught of abuse of logic, men made of
straw, mathematical sleight of hand, and alternative science has proven
too much for one person to endure. Personal intergrity has succombed to
vested interest, and I must withdraw. The internet may once again be
put to a good use. ;-)

Yep, in order to avoid your inevitable copout: "But that's
not steady-state." There are natural noise glitches existing
in every real-world steady-state system. Those natural noise
glitches can be used to track the flow of energy in the EM
waves.

In the real-world, a system never achieves true steady-state
conditions because those natural noise glitches are always
present and, unfortunately for your argument, can be easily
tracked.

I keep telling you that the only technical disagreement
we have left concerns only the minutest of details
after semantic adjustments have been made to account
for our differing definitions of words.

According to your definition of "convey", the energy
associated with EM waves isn't necessarily conveyed.

According to my definition of "convey", the energy
associated with EM waves is necessarily in the process
of being conveyed.

I'm obviously talking about the different definitions of "convey"
that you and I use. By your definition, the pack mule is never in
the process of conveying a person down the path into the Grand
Canyon. Conveyance of the person cannot be verified until the
person dismounts. If the person never dismounts, the pack mule
never was conveying the person. IMO, that's a silly definition.

Yet, barring unexpected removal of the load from the system, most
hams are intelligent enough to predict conveyance of energy from
the source to the load. Otherwise, what would be the purpose of
getting on the air?

I try to stick to common usage of words. Sometimes I'm wrong,
as I was about "non-glare glass". When I discover a mistake,
I am quick to admit it, correct it, and move on. Others, incapable
of admitting mistakes, would simply have pleaded an esoteric
definition of "glare" in an obvious CYA move.

Some posters delight in uncommon usage of words at the expense
of the majority of readers. I won't name any names. :-)

> Truly English is a dead language here. There is more effort expended
> in trying to find the Rosetta stone for its interpretation than the
> performance of bench work or simple computation.

Actually, there is a lot of effort expended in trying to under-
stand the words describing the previous bench work. Doing so
is simply an efficient use of time and effort.

For instance, I could expend a lot of time and effort duplicating
on the bench what has been reported on those two optics web pages.
But I am satisfied that they said what they meant and meant what
they said, i.e. wave cancellation (destructive interference) in
one direction causes a redistribution of the associated energy
(constructive interference) in another direction. Remembering that
Walter Maxwell said the same thing in "Reflections" a quarter of
a century ago is icing on the cake.

I see the North Star on a clear night through detection of
photons. What does it matter how many photons I am detecting?
There's more than enough to detect. And every one contains
energy "conveyed" from Polaris and "converted" by my retina.

Cross-posted to: alt.ham-radio.vhf-uhf,rec.radio.amateur.antenna,rec.radio.swap

1-Cushcraft AR6, 3db gain 6mtr vertical antenna.
Universal Radio price $74.95

$35.00 for pickup in SE, Pa. only.

pottsladd13@yahoo.com

AR6 Specifications
Frequency: 50-54 MHz
Gain: 3 dBi
VSWR 2:1 Bandwidth: >2 MHz
Power: 1000 watts FM
Height: 10.1 Feet (3.1 m)
Ring Diameter: 13 inches (33 cm)
Mast Size: 1-1.25 inches (2.6-3.2 cm)
Wind Surface: 0.37 sq. feet
Connector: UHF
Weight: 2.5 Lbs (1.1 kg)
Specifications are subject to change without notice.

1-DiamondX510MA (UHF connector)

The Diamond X510NA was designed for strength and performance and is
pre-tuned to achieve maximum gain in both the 2m and 70cm amateur bands.
(2m: 3 x 5/8 and 70cm: 8 x 5/8). It has a 3 section fiberglass radome with
overlapping outer shells for added strength. It comes with stainless steel
mounting hardware and radials and strong-waterproof joint couplings.

X510NA Specifications
Frequency: 2M/70CM (144-148 and 440-450 MHz)
Gain: 8.3/11.7 dB
Power: 200 watts
Connector: N
Height: 17.2 feet
Weight: 5 Lbs.
Wind Rating: 90 MPH
We also carry the Diamond X510M which is the same antenna, but with an UHF
(SO239) connector instead of an N connector.

Universal Radio price $188.95.00 new.

$115.00 for pickup or meeting in Se, Pa. only.

Clearly the understanding of the English words "How much energy" sets
the bar too high for this technical forum. That, or the experience
with the subject matter is so limited as to render the poster's
response in xeroxed cut-and-paste platitudes. An undocumented worker
could easily provide material of equal quality.

I could go look up the quantitative energy calculation
and post it. But nobody in the world would be better
off because of my effort. Therefore, I would rather
spend my time doing something more enjoyable like
swigging Merlot.

Hi Fred, The orginal poster referred to the Buddipole antenna which
is a commerical antenna sold by that name. What you are thinking of is
2 mobile Hamsticks mounted on a bracket configured as a dipole. Other
than them both being dipoles, they are not that much alike.
The Buddipole is very light weight, covers 40m-2m by adjustment of
loading coils, and element length. I have seen people walking around
at hamfests using them, they had a harness like one would use for a
flag in a parade to support the "mast". They had one of the little
Yaesu Xcvrs (817?) strapped to their back, and were in QSO with
somebody, may have been a guy in the parking lot with a mobile.
The Hamstick dipoles are about the same length (16') but are heavier.
The efficiency is probably less on 40m and 20m due to the loading

schemes. To change bands you have to have aquire 2 more Hamstiks for each band you wish to use. The Hamsticks can do 80m and maybe 160m, but they are near dummy loads on these bands. The Hamsticks seem to have more "sag" than the Buddipole.
As I stated in my previous post, I would hate to have to rely on either as my primary base antenna.

4171. one and a half meter US amateur band: antennas for 225Mhz, or CH 12-DAB ..

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-10 23:13:31 UTC
From: Debbie H <markovREMOVETHIS@tele2.be>
Message-ID: <markovREMOVETHIS-0439E1.01132811082005@nn2.swip.net>
Source record: 71939
Cross-posted to: rec.radio.shortwave,alt.radio.digital,rec.radio.amateur.antenna,rec.radio.amateur.dx

I have a Digital radio and reception of one packet on 225Mhz is poor.

This sentence gives me hope:

"DAB is very close to an American (not European) amateur radio band (the
220-225 MHz or one and a half meter band). It is therefore possible to
find suitable instructions for building an own aerial in American
amateur radio publications".

Anybody can point me to such a publication??

I have a general band III TV antenna, designed for 170-240Mhz,
but the station is on 225Mhz, so thats on the upper side of the
band. I already "redesigned" a yagi antenna and made the
directors closer to each other, but do not know the exact size,
or maybe there is some simple design that makes the signal boom.

Is there a publication/calculation to design Yagi's?

(I built a loop for ~500-1850khz and I'm dreaming of a loop antenna ;-)

Thanks,

Marc

Hi Tom,

A strange rule indeed. If we examine your sentence, the commas set
off a parenthetic. A parenthetical can be withdrawn without changing
the sense of what was written:
>I thought the rule was than too few.

Commas also set off constructs that might be moved to another part of
the sentence without changing the sense of it:

According to Strunk and White, in a short sentence you can discard
what would have been mandated by normal rules.

In a short sentence you can discard what would have been mandated by
normal rules, according to Strunk and White.

In a short sentence, according to Strunk and White, you can discard
what would have been mandated by normal rules.

Compare:
>I thought the rule was than too few, better too many commas.
(a grammatical structure which almost describes total cancellation)

>Better too many commas, I thought the rule was than too few.

I am quite sure you were pulling our leg. Others express extreme
difficulty with language as though it was their first time applying
for a green card.

One of my favorite conservative writers had an amusing comment on the
nature of this language difficulty here in Seattle with taking the
Drivers exam:
The written test wasn't hard. You had a choice of English or
Spanish. If you couldn't read either language, they waived the
test and automatically gave you a taxi license. I passed in
English.

The road test was more of a problem. Seems that I had a burned-out
turn signal. Seems the evaluator, an attractive but sternly
imposing middle-aged woman, noticed. Since this was a real street
test in real traffic, procedures required that I use hand signals,
which I hadn't used since taking my initial test several decades
before. Soon I was flailing madly, bumping cars as I tried to
parallel park, running stop signs, cutting people off. The

evaluator said nothing, but with each check mark she made on her clipboard sheet, I grew more flustered. Finally, I gave up and said:

Look, this is the way we drive back East.

Not in my state, you don't.

I'll be good. Promise. Can I have my license? Please?

She glared, but passed me. I took my paperwork to the issuing counter.

Would you like to register to vote while you're here? the clerk asked.

OK. Put me down as Republican.

Registration is nonpartisan. Would you like to be an organ donor?

Sure. Can I leave my organs to Republicans?

Wrong thing to say. But at least I wasn't from California.

Jim, AC6AG wrote:
"The thing you really need to consider is how much energy is actually
"in" a wave (whatever that means) that delivers no energy."

If it delivers no energy, it has none to deliver. That`s common knowledge. Most antenna systems are highly efficient. Nearly all delivered energy is radiated. Look at a few radiation patterns. Sum the watts per square meter in all the equare meters surrounding the antenna, and the power very nearky totals the power fed the antenna. The total watts are independent of antenna pattern.

Watts per square meter suppressed in one direction, appear in other directions. Power is not annihilated by cancellation. It is redistributed in other directions. Power can`t be retained in the cancelled directions because it would then be unavailable for redistribution. We know that is not the way cancellation works. The cancelled energy is redistributed.

Long ago, a fellow named Young demonstrated how wave interference works in a famous experiment now named for him. You likely have seen this experiment in a physics lab near you.

Young squeezed light from a common electric lamp through a narrow slit to serve as a light source for two more parallel slits farther along. The light from the latter two slits illuminated a projection screen.

The screen display is seen to consist of alternate bright and dark bands. This is explained as caused by the difference in path length between the two illuminating slits and the bands on the screen.

The bright bands result from constructive interference where the difference in path length from the two sources is an even number of 1/2-wavelencths. For example, two 1/2-wavelengths makes 360-degrees. Such phase rotation produces the same phase as no rotation whatsoever.

The dark bands result from destructive interference where the difference in path length from the two sources is an odd number of 1/2-wavelengths. For example, a phase rotation of 180-degrees corresponds to the odd number (1). Two equal and opposite waves add to zero and produce darkness in a particular band space of the display.

This interference display is an old game that is often presented in a high school physics lab. Sometimes it is done with pinholes replacing the slits, but slits make a brighter display.

I used to think that Joseph F. Schlitz really made the brightest display!

Best regards, Richard Harrison, KB5WZI

4179. Required radials on DX-88

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-11 02:16:24 UTC
From: Topaz305RK <k7sam@arrl.net>
Message-ID: <2PqdnWgfBfMoKWffRVn-rA@vnet-inc.com>
Source record: 71947

Am in the process of installing a Hy-Gain DX-88 that I just picked up. It has the 160 meter kit included. According to the manuals I should install 16 radials at 14 feet each if just using up to 80 meters. If I plan to use 160 meters than I should also install another 16 radials at 24 feet each.

The question: Would I better off to install all 32 of these radials (as per the manual) or put down 4 radials cut to 1/4 wave length for 10, 12, 15, 17, 20, 30, 40, 80 and 160 meters? Putting down 1/4 wave radials on 80 and could prove to be a problem real estate wise. I am out in the country but even then I still have some limitations.

Here in the states, the 1.25m band follows normal ham operation practice.
a vertical polarized antenna cut to about 31cm or so as a 1/4wave antenna
over four radials works well for FM operation where as horizontal works well
for SSB

You shold be able to find decent plans for a 1.25 beam in either a ARRL,
JARL, or RSGB publication, or use or friend Mr. Google on the interweb.

Or, you can tell them what frequency to make the beam for at
http://www.arrowantennas.com/. Pretty darn good and cheap antennas I use
a few UHF beams here and the combo 2m/70cm beam for portable ops

Hi Richard,

This is so totally overwhelmed by negative example:

Let us consider that you as an amateur, transmitting at 100W seeks to deliver all the energy of your radiated signal.

Let us arbitrarily assign 100% antenna efficiency, and absolutely no ground loss - all 100W are indeed RF and radiating outward to the dictates of a perfect, lossless, world wide distribution.

Let us further consider that every man, woman, and child on this earth has a radio and is listening to you at S-9 signal strength.

They consume
(6ï¿½10^9) ï¿½ ((50ï¿½10^-6)ï¿½ Voltï¿½/50 Ohm)
(6ï¿½10^9) ï¿½ (50ï¿½10^-12) Watt
300 mW

In other words 99.7W has never found its way to any listener and we know full well that the entire population of earth would never hear you on any Ham frequency. Nor would a significant number for who did, would it be as good as S-9 for that 100W signal.

To say 99% of your energy simply evaporated away, to no purpose whatever, would be over generous by 10,000 fold.

However, the point of this much energy is to establish the fields to allow those who do hear you, to hear you at that S-9 level (or better, or worse). Without this tremendous energy effort, transmitting only the energy deemed to be for delivery would confine us to telephones (and the losses there are hardly worth crowing efficiency).

Even talking to your buddy as you cross an open field together is vastly inefficient (energy-wise). Unless, of course, global warming is not perceived to be a problem (sound energy is heat, phonons; RF energy, photons, is not always rendered into heat).

Hi Richard,

Hmmm, a syllogism.

If it exists as a wave, energy is the root of its existence. If it delivers no energy, "it" still exists, but so does some other "it" exist with an equal, counter impulse. Cancellation is not a solitary act. A Cancelled wave is not a single entity. In fact, both energies have been delivered to a load (waves do not act upon each other in a vacuum), and have balanced out to create the condition of "nothing being delivered."

Otherwise the discussion rather fancifully pivots in a void of non-waves, not existing and we could then introduce "King Lear" and his observation that "nothing begets nothing." Should I point out that Lear was a pathetic loser?

>After all, power is limited in capability. If it still exists in its >cancellation, it can`t be acting elsewhere.

And we return to the excess energy of the thin film reflections after "total" cancellation. Nice to see that the topic is still being discussed. ;-)

Probably you are the only reader of Richard Harrison's post who took it to mean that a radio wave is an efficient means of transferring power from one point to another in an uncontrolled propagation environment.

Though you chose not to include it in your response, Richard Harrison's next sentence of that post reads, "Nearly all delivered energy is radiated." He did NOT write that nearly all radiated energy is delivered, which apparently is the way you understood it. A bit of dyslexia, perhaps?

As even you must know in lucid moments, most practical transmitting antennas ARE highly efficient at converting the power applied to them into EM radiation.

The "coverage" provided by an antenna is defined by much more than its radiation pattern. Overlaying the radiation pattern on a map is almost useless in determining coverage except in a very general way.

Some of the other factors determining coverage are:

- Frequency
- Time of day
- Season of year
- Sunspot cycles
- Terrain profiles
- Earth conductivity

Coverage software is available that considers the most important factors. I am familiar with the versions applying to AM/FM/TV broadcast, but not for ham radio. I imagine someone else will post info leading you to that.

Marc and Richard

UKWTools will give you coverage plots based on, terrain, ground type,
freq, antenna gain using the Longley-Rice model. Freq coverage I think
is from 20MHz to 20GHz but doesnt (obviously) include ionospheric effects.

It uses SRTM and GTOP30 terrain data, is GPL and available for both
Windows and Linux

It does not give a coverage plot for gain in a specific direction. It
assumes the gain is omnidirectional.

Found here http://www.qslnet.de/member/g4klx in the Software section

Feel free to ask me more about it or provide an output sample,

Cheers Bob VK2YQA/W5

The radiation pattern can, of course be obtained from EZNEC.
Free demo version available at www.eznec.com

The azimuthal map can be obtained from PIZZA.
Free at www.tonnesoftware.com

These two can be overlaid to obtain the graphic that you
desire. The latest version of PIZZA is supposed to take the
output data from EZNEC and plot it centered at a point on
the earth. I haven't had time to try the new version yet.

As Walter Maxwell said in "Reflections" a quarter of a century ago:

"The destructive wave interference between these two complementary
(reflected) waves ... causes a complete cancellation of energy flow
in the direction toward the generator. Conversely, the constructive
wave interference produces an energy maximum in the direction toward
the load, ..."

We can have an incident and reflected wave or an incident and reflected impulse. The reflection is not contemporaneous with the incident in their generation. The reflection was generated earlier and is on its way back. Power generation remains constant regardless of wave interference, at least until the reflection arrives at a point where it interferes with generation.

Complete cancellation leaves zero energy on the path of the cancelled wave. "It" isn`t "two opposite somethimgs". "It" is zero. Energy cancellation on one path redistributes the energy on other paths or directions.

Power is energy generated at some rate. A fixed rate means that after total cancellation, redistrubited energy is the total, and cancelled energy is zero. You can`t have your cake and eat it too (to coin an expression).

Hi Richard,

I see you prefer to look at the world like King Lear and mumble "Nothing begets nothing" then. This is all fine and well, but it leads to unnecessary elaborations like:

>Power is energy generated at some rate.

It certainly is, but Power has nothing to do with cancellation except as a proof of two wave's energies combining to nothing. This is not a "Nothing begets nothing" argument. Two energies pass without interaction unless there is a load.

: A fixed rate means that after
>total cancellation, redistrubited energy is the total,

It was, is, and will always be the same total, that is the meaning of conservation of energy. Time alters nothing but the ability to push a load around to map the distribution of power. Power is the summation of all energies into a load.

>and cancelled energy is zero.

There is no such thing as cancelled energy short of a Nuclear folding of the universe. No, the total contribution of two energies into a load is zero power. Each of those energies remains to contribute to all fields or they would never propagate.

> You can`t have your cake and eat it too (to coin an >expression).

Then you need to make your choice, are you eating (power), or are you having (energy)? To attempt to say they both live by the same rules is going to leave frosting on your face.

Richard Clark wrote:
> Two energies pass without interaction unless there is a load.

The exception to that statement is two coherent waves traveling an identical path in the same direction. If the two waves are of equal magnitudes and opposite phases, they cancel completely in their original direction of travel. In a transmission line, their combined energy components reverse direction in order to satisfy the conservation of energy principle. In the absence of any additional sources or loads, destructive interference energy must exactly equal constructive interference energy.

The above can occur at a lossless impedance discontinuity in a transmission line - no load required.

> Power is the summation of all energies into a load.

Often power is simply the joules/sec existing at a unit-area plane or passing a point on a transmission line. The power-flow (Poynting) vector doesn't require a load. All it requires is an EM wave.

Well, it would be easier if you didn't delete the
context. I assume you are talking about the energy
components associated with the canceled waves, traveling
rearward before the cancellation and traveling forward
after the cancellation where the cancellation is a
continuous process (until source power is turned off).

In s-parameter terms, the two joules/sec components are
(s11*a1)^2 and (s12*a2)^2 when b1^2=0 as explained in the
HP Ap Note.

In ham terms, they are Pfor1(rho^2) and Pref2(1-rho^2)
where Pfor1 is the forward-traveling source power incident
upon the impedance discontinuity and Pref2 is the rearward-
traveling reflected power incident upon the impedance
discontinuity from the other direction.

Note that I am using common usage terms for "forward power"
and "reflected power" since their units are watts. I would
normally talk about "forward energy" and "reflected energy"
to avoid the wrath of the purists. :-)

In terms of my article, they are P3 and P4 where:

P3 = Pfor1(rho^2) and P4 = Pref2(1-rho^2)

Pref1 = P3 + P4 - 2*Sqrt(P3*P4) = 0

Source record: 71969

Anyone install a 2/440 rig in a 2005 Silverado? I will be soon and was just wondering if anyone had been through it and had any advice that may help. Where you can route power cables or coax throught the firewall. Perhaps a good place you can pick up power form under the dash instead of going to the battery. If I decide to roof mount an antenna, what is the best way to make the hole for an NMO mount in the roof? Any experience with HF in the 2005 Silverado? Noise problems? Any RFI getting into any components of the trucks electronics?
I have an IC-706 and a screwdriver antenna I may want to use in it. I had no problems in my old 1990 truck but not much electronics in it compared to the 2005 (the employee discount GOT me)!! Thanks, Mike K7MH.

I run 100W from my IC-706 through the aux cigarette lighter
socket. My 1996 GMC Sierra has a cigarette lighter and two
aux sockets. In my pickup, they are reasonably "clean" and
I have no complaints. I also have the IC-706 grounded to a
seat belt anchor bolt and use the remote head cable.

Richard Clark wrote:
"There is no such thing as cancelled energy short of a Nuclear folding of the universe."

Most would agree to energy conservation.

Young`s experiment produces alternating bright and dark nands.

The bright bands are brighter because they contain redirected power that would have appeared in the dark bands as well as the power idirectly lluminating the bright bands. In the bright band spaces, power is in-phase from both source slits. In the dark spaces, power is 180-degrees put of phase between the illuminations from the two slits. This is caused by the distances from the two sources.

At the risk of diverting attention from the topic, I`ll indulge in analogy. An impedance bridge has a null meter to indicate balance. Superposition says a circuit with two (or more) sources may be analyzed (with proper restrictions) as if there were only one source in the system. That is, respones to the various sources may be analyzed separately to determine the overall circuit response.

A balanced bridge may be considered as two voltage dividers set for the same ratio and providing identical voltages to each terminal of the null meter. Each divider taken alone provides the same fractiom of the bridge generator`s voltage. Alone, each divider can supply current through the null meter.

Equal and opposite ciurrents don`t flow through the null meter. No current flows through the null meter because with equal and opposite voltages on each side of the null meter there is no difference of potential to evoke a current flow.

Given a perfect transmission line with a complete reflrction, a length can be found which produces a reflection with with the same phase and magnitude as that of the generator. With equal and same phase volts on either side of the generator/line junction, current does not flow. No potential exists to evoke a current flow. This is the same as a very high impedance indeed.

Best Regards, Richard Harrison, KB5WZI

The deletion was deliberate because energy does not move and is an
irrelevant embroidery of the discussion. Of course, if this is about
rolling batteries across the floor, I've yet to see how much "power
has been delivered" revealed in these threads.

4206. 40 Meter local prop theroy question

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-11 18:05:17 UTC
From: Ken Bessler <kg0wx@NOSPAMyahoo.com>
Message-ID: <xrMKe.243$ct5.30@fed1read04>
Source record: 71973

Assuming 2 identically equipped stations operating
mid day on 40m SSB, how far apart would they have
to be to see differences in propagation from a station
say 500 miles away?

Remember - both stations are identical - same rig, same
antenna (Inverted V @ 40'), same local noise levels, same
radiation patterns.

What I'm trying to visualize is the way a given signal hits
a city and whether an instance where station A can hear
better than station B is a problem with station B or simply
propagation patterns of an inbound signal.

Hope that makes sense..... lol!

> No potential exists to evoke a current flow.

Hi Richard,

The potentials (energy) abound, you even describe them. The sum of all voltages (energy) equal zero at balance (absolutely no power into the load of the meter), but that does not mean there has been any cancellation of energy - that is glaringly obvious. Remove the load, and you can set the bridge adjustments ANYWHERE and there would still be no interaction of energies.

At absolutely every segment of the circuit, there is a potential difference, and all must exist to present the null (which is evidence of a potential difference of zero, not evidence of no potentials). This is Kirchoff's law in the raw.

Contrary wise, removing the source of energy will give an exactly identical reading on the current meter, and to say that no energy is the same as balanced energy is a shuffle on par with the old shell game - King Lear muttering "Nothing begets nothing."

For cancellation of energy to exist, your analogy proves there must be an identical energy present to offset it. This explicitly admits energy remains in the face of narrowly inspecting an isolated instance of balance (or cancellation - all the same, only a matter of topology).

Net current doesn't flow. But a circulator and load will
separate the forward component from the reflected component.
For instance, at a point on a transmission line where the
net current is zero, the forward current may be 100 amps and
the reflected current may be 100 amps, just out of phase with
each other.

In your above example, if the source is a signal generator
equipped with a circulator and load resistor, the net current
at the signal generator terminals can be measured to be zero
while the circulator resistor is smoking. Thus the difference
between distributed networks and lumped circuits.

One possibility is that the source simply delivers less energy.
One possibility is constructive interference.
One possibility is additional dissipation.

Hi Ken,

If they (A and B) are separated by your local city/town/village, then
the common sense of the broadcast model would suggest that both of you
have an equal shot at it. Otherwise the entire broadcast industry
would have collapsed in the late 20's from lost listenership.

When I put this kind of test to a propagation modeler, and I tighten
the beamwidth of the antenna to 10ï¿½, then after the first hop, the
signal covers an area larger than a 70 mile wide county with its
footprint. I don't think your cross-town buddies are going to be left
out in the cold, if all things are as equal as you suggest.

Given the problem as you have stated it, get station B to check his coax or connectors etc. It is remotely possible, but unlikely that propagation would be the culprit.

I made the assumption you were not is a city that is spread over several hundred miles.

If you wish the crutch of illusion, the photon moves, the energy is in its wavelength. You may analyze the photon as a wave, or as a particle, but none of the energy is ever destroyed - short of collision with an anti-photon. Reflection, interference, what-have-you never presents us with opportunity to indulge in nuclear pyrotechnics. If the sun were suddenly replaced with its equivalence in Dark Energy, I don't think we would freeze.

4216. Sony kitchen radio antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-11 19:42:04 UTC
From: jeplett <jeplett.1tmc08@news.radiobanter.com>
Message-ID: <jeplett.1tmc08@news.radiobanter.com>
Source record: 71885

Hi radio folk. Not sure if this is the right forum for this post, but here goes:

I have one of those white under-cabinet Sony kitchen radio / cd players. The radio uses a digital tuner. They have notoriously poor radio reception, and the internet is full of posts by people ranting about how Sony could sell such a poor radio.

Rather than rant, I thought I'd ask you experts if there's anything that can be done to improve the reception. I understand the power cord is used as the antenna. I've tried stringing-up an extension cord to the power cord, with no improved reception. Could I open it up and attach an external antenna? If so, how would I do this? Any ideas, or experience with this particular problem?

Regards,

--

Some of the other responses seem reasonable for average propagation. However, I wouldn't be surprised to see short-term variations (on the order of seconds to minutes) up to tens of dB between antennas placed as close as a wavelength or less, due to multipath propagation. You've undoubtedly seen this as the "picket fencing" you get when using a mobile VHF or UHF rig.

So what? It hasn't been legal to operate a spark transmitter for a couple generations. You don't even have to be a ham to build, just pick up some of the early books and follow the instructions. The receivers of that era would be useless in today's congested RF spectrum, as well.

On the other hand if you can design and build a state of the art communications system without outside help, that is something to brag about.

Hell, I'd be happy if a significant percentage of the late vintage
extras, who have "proved their worth" at 20 WPM, could operate worth a
damn. I know techs who have better manners and know more about traffic
handling.

Note that I said "late vintage".

I do wish people would not refer to me as a 'ham'.

Amongst the very few things I am proud of is that I am a true Class-A Radio Amateur.

Incidentally, as a British pensioner, my annual licence is free. When requested I just have to confirm I am still in circulation. Same applies to riding on buses when mobile or not mobile, sober or not sober.

Arn't you American Amateurs envious?

Reg, G4FGQ.

I can't imagine why we should be. I've been a ham for nearly 50 years (Extra class for more than 40) and have never paid a cent for my license (or my commercial FCC licenses, for that matter). Can't recall the last time I rode on a bus. But the 17.5% tax I'll pay on everything I buy in your fine country during an upcoming trip will be my small contribution to your continued enjoyment of your lifestyle. Then I'll return to Oregon, where we have no sales tax and I can ride on the light rail for a couple of hours for a bit under a pound. Even for those of us who aren't pensioners.

Roy Lewallen, W7EL
Ham.

What frequency? The last system I worked on was a 70 MHz IF with a
90 MHz upper limit for a dual channel telemetry receiver with a
diversity combiner all done in the digital domain.. It was the
L3-Com/Microdyne RCB-2000. It also had a 70 MHz IF output that was
regenerated after the FIR filters to feed wideband logging recorders for
later analysis. Multiple IF bandwidths and Video bandwidths. It was
controlled by a custom GUI under embedded NT, and had IEEE-488, RS-232
and Ethernet ports for remote programming and control. All for just
$80,000 per radio.

The DR-2000 was the same basic radio chassis, but it was just single
channel receiver.

Hello Bob,

the message "Error: Wire 5, seg 91, Ex-src: Not allowed near open wire-end" is not correct. At least not when a TL is connected to the wire. May I ask what 4nec2 version you were running, because I thought I had solved this 'problem' already some time ago.

Thanks in advance,
Arie.

Sam,
Install as many 35 foot or longer radials as possible. They will work
fine for the higher bands, ie, 20-10 meters.
Radials do make the difference.
Good luck,
Jim, K4SQR

Source record: 71909

To all

Thanks for the answers.

I should have precise that I was looking to overlaid "HF" horizontal antenna patterns with azimuthal maps.

2 software for the azimuthal maps :

- from SM3GSJ software GCM : free, simple, and does work well

http://hem.passagen.se/sm3gsj/

- and PIZZA : will be fine if it does interface with Mininec, Eznec, ...

I do understand that HF propagation (long distance, iono, ...) is an other topic.

However, I would like "first" to understand "the effect of terrain" on the vertical patterns with software like

Terrain Analysis K6STI or HF Terrain Assessment N6BV (see my specific post on that).

Note : Thanks for the links for VHF - UHF programs such as : UKW Tools G4KLX or Radio Mobile Deluxe VE2DBE

BTW, that was a joke. Being retired, I don't know what the upper
frequency limit is for DSP sampling nowadays. I was using one
million samples per second systems at Intel ten years ago.
They worked well at 455 kHz not only for filtering but for
decoding/detection.

Cecil, I thought you and I did our 'DSP Filtering' by adjusting the
regeneration control or the whisker.

What's an IF ?? IF! If What??

Strangely enough, I never used anything except a superhet.

> What's an IF ??

455 Khz on everything I used back then. With no RF amp,
my S38 would receive the same signal on two different
frequencies on 15m, sometimes eliminating an interferring
signal in the process.

Cecil, without the RF amp to erase the image, the S38 could boast
two-fer-one, or double yer pleasure--two places to get yer
information--you could take yer pick. The filter in that unit was a
Gilette double-edged type.

Walt

Actually, I wanted to build the amplitude discriminator filter
described in the April 195? edition of QST. With back to back
discriminators, it blocked the strong signals and let the weak
ones through. Larson E. Rapp certainly performed miracles with
unusual electronic designs back in those days.

One time the BFO oscillator cap failed in my Hallicrafters S53A.
Shorty (W5 Old Lonely Virgin) the local TV repairman, didn't
have anything that small so he showed me how to twist two wires
together until I got the right beat frequency.

I would have loved to stick with my assigned call when I moved
from TX to CA in 1971 but the FCC forced me to give it up. Now
they have charged me the social security money they gave me to
get it back.

Well for myself I wouldn't have picked the spaghetti soup group of letters I had to
start with. But after retiring I thought I might as well get a little vain... That's all
that left after a while. he he.... So for a whopping $20 I got a vanity call after
moving to a new call area. I thought in my second life after heart surgery, back surgery,.ect. I might as well have a little fun. After all isn't that what a
hobby is for? I'll get 10 years out of my new call but I can't get that far on $20 worth of gas these days. eh. Now all I need is about $20K for that new $13,000 ham radio and a tower and antenna ha ha.

What ever is fun is ok. Even if it means dumping a 25 year old call sign.
Let me see Ham radio so varied what next.
Been there done that.... DXCC... RTTY... OSCAR.,.. PACKET...
oh and of coarse RAG CHEW codey slow no problem getting in the time for that award. Contest... Special events... Homebrew...
and a cold brew...

Oh BTW it isn't the one with the most toys... It's the one who gets to play the most with their toys. Have fun everyone and don't take it too seriously or you get an ulcer and high blood pressure.

Cheers 73 ol' WB9SMX new K4TWO when the papers arrive. ;-)

Wow. I've just tried this using the .csv output from MMANA and
converting via excel. The output of 4NEC2 works as well. I was able plot
the 4 antennas we used on the UK VHF NFD recently very quickly.

There's a couple of bugs. The locator square seems to be one small
square out and I get a glitch on a couple of the patterns. Otherwise
it's pretty good.

Dave -

4 Meters is not available for amateur radio usage in North America. RSGB would be a logical reference source ... or adopt existing 6 meter or commercial FM broadcast (88 - 108 MHz) designs

A standard 1/2 wave driven element will be approximately 6 feet (or 2 meters) in length.

Uhm -rec.radio.amateur.antenna is a world-wide newsgroup

I find RSGB antenna designs to be disappointing. FM broadcast antennas
are too broad band. There is more mileage in scaling 6m designs, but you
can do your own better optimised design for 4m since it is only 500KHz
wide. I've an 11 element on a 15m boom -but its bandwidth is only
200KHz.

There is a good design here with construction details.
http://www.g1ogy.com/G4ZTR/4Mbeam/G4ZTR4mbeam.html

There are others if you search.

Cecil, W5DXP wrote:
"Net current doesn`t flow."

I`m inclined to agree, but at first current flows with a volts to amps ratio rqual to the Zo of the line until a reflection returns to the connection point of the stub. Then the total phase rotation within the stub has reached 360-degrees. The complete reflection supplies a reflected voltage wqual to the incident voltage. There is no difference of potential or phase to evoke current. It`s the equivalent of a very high impedance. Almost no more current is motivated to flow, once the steady-state condition is reached.

Alexander Wing wrote on page 29 of "Transmission Lines, Antennas, and Wave Guides":
"Suppression of Even Harmonics.- An application of a short-circuited quarter-wavelength line is to suppress any unwanted even harmonics in the output of a radio transmitter. A short-circuited one-quarter wavelength long at the desired output frequency may be connected across the output terminals or across the antenna feeder at any point without placing much load on the transmitter at the fundamental or desired output frequency, since at this frequency such a section has an impedance ideally infinite, actually about 400,000 ohms."

How much current flows into 400.000 ohms?

Best regards, Richard Harrison, KB5WZI

Just because your feedline is 450 ohm doesn't mean that the antenna
impedance is 450. A center fed zepp is a high impedance feed,
probably above 1000 ohms. The reason for using open wire is to
minimize loss in the line, open wire is very low loss.

Also, depending on the length of the open wire, it could act as a
transformer, changing the impedance.

Feeding it into a 4:1 balun will drop the impedance but if the balun
is feeding a 1600 ohm load, the other side of the balun will see 400
ohms, certainly not a match for coax, or for your rig.

Richard, some people use that exact same argument to try to prove
that no current is flowing in the middle of a transmission line
where forward power equals reflected power. The strange thing is
that the current 1/4WL away from that zero net current point is
sky high.

If the current 1/4WL away from your above source output terminals
is indeed sky high, it is because the forward and reflected currents
are in phase at that point which means they are 180 degrees out of
phase at the source output which means they are both still there.
If the net current is zero, all it means is that |Ifor|-|Iref| = 0.
It tells us nothing about the magnitudes of Ifor and Iref.

Trying to treat a distributed network as a lumped circuit can lead
to mistakes.

>
> How much current flows into 400.000 ohms?

How much current flows in the shorted end of the stub? Let's say we
measure it at 2 amps. Where does that current come from?

The 400,000 ohms is (Vfor+Vref)/(Ifor+Iref) at the mouth of the stub
where V's and I's are phasors. Knowing that (Ifor+Iref) is a small
value doesn't tell us anything about the magnitudes of Ifor and Iref
except that they are nearly equal as is always the case for a
low-loss stub. Knowing (Inet=|Ifor|-|Iref|) is small doesn't tell us
a thing about the magnitude of (|Ifor|+|Iref|) that exists at the
shorted end of the stub. Does that make sense?

You might be an old time if you can answer the following, with out diving into your library.

Which of the following is NOT a rectifier?
a. 3B24
b. 80
c. 3C24
d. 6H6

Steel wool was once touted as a good material to make which of the following?

a. Choke Balun
b. AF shielding
c. Linear capacitors
d. Radials for short virticals

Feel free to add your own favorite...

Good ones, Fred, 3B24 and 3C24 are not rectifiers.

However, some moron claimed in QST that steel wool was just as good as ferrite for making choke baluns, but I've forgotten who the lunkhead at the League was who believed him, and allowed stupid idea to be published.

I complained to the League editors, who unbelieveably said 'Prove It'. So I bought some steel wool and made two back to back baluns with it and made measurements of common mode currents. The measurements proved that the steel wool had absolutely no choking effect.

I reported the results of the measurements to the editors at the League, but I can't remember whether they did anything about refuting the original incorrect material. Perhaps your memory is better than mine on this issue.

Close Walt, only the 3C24 was not a rectifier. Sit back, light up the pipe, and remember the purple glow of the 3B24. You were right on about the steel wool. I was wondering how many would remember the dufus that was trying to tell us that steel wool and a paper towel roll was as good as ferrites.

I also wrote a letter to editor. I was a bit more sarcastic requesting the B/H curves of steel wool.

The results of your measurements were published in "Hints & Kinks" in September 1993 QST. According to the editorial comment accompanying it, you were prompted to make the measurements by Tom Rauch, W8JI, who had done some measurements which indicated that the steel wool balun was ineffective. The Hints & Kinks editor at the time, who had accepted both the original contribution by Curt Wilson, W0KKQ and yours, was Dave Newkirk, WJ1Z. Anyone interested in learning more about it should read the Hints & Kinks submissions and note Dave's added editiorial comments.

One legitimate ;) use for steel wool was what we used it for as kids.

When the cops cited us with a repair order for a too loud exhaust
system on our hot rods, we would stuff steel wool up the pipe and
secure it with a rusty nail in cross-drilled holes.

We would then find a handy cop and ask him to sign off that we had
fixed the problem. He would usually ask us to rev up the engine and
we would hope like hell that the steel wool didn't come flying out at
the wrong time. I think most cops were on to this but they played
along.

Here's a ham-radio related use. I've got a bunch of it stuffed into the ends of the buried PVC pipes carrying my feedlines into the back yard, in an attempt to keep the rodents from using it as a highway. Seems to be working so far. . .

Well, you can roll your own, but the easiest way is to just go to a
shop that installs business radios, and have them make the hole and
run a piece of coax to wherever you want it -- they do it every day.

Down here in the desert the pack rats would just say, "Thank you very
much, do you have any more?"

When my wife's office at Hughes had a problem with rodents coming
through an A/C receptacle in an exterior wall the plant maintenance
guys used either copper or bronze wool. Seems to poison them.

My problem isn't rodents in the house, it's scorpions. Killed two of
the things just last night. I'm remodeling a bathroom, where most of
them show up. I told my wife I think I'll install some UV lighting so
I can see them easier. (They fluoresce under UV.)

4266. Re: Removal of Morse Code from Amateur License Requirements...Vanity call wheeee

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-14 02:50:57 UTC
From: Rick Frazier <rickf@rickfrazier.com>
Message-ID: <42FEB19E.7AAABA57@rickfrazier.com>
Source record: 71834
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.digital.misc,rec.radio.amateur.equipment,rec.radio.amateur.misc,rec.radio.amateur.swap

Though this appeared in the Rec.radio.equipment newsgroup and is being broadcast to several others that may or may not really be appropriate for this diversion from the original subject, I can't help but responding....

When it comes to a vanity call, the relative pittance we are charged for a call that makes sense to us (whether because of an old call in another location, or because it's easier to transmit in morse, or even fits some other plan we may have) is worth the money in my opinion, and I imagine to anyone else that took a vanity call.

For myself, I chose my current call because the people at FCC didn't give me a call in my area on an upgrade from Tech to Extra, despite an address update way prior to the examinations. Somehow, they managed to show correct postal box address and city, but my state as California (where I used to live), yet the zip code was correct, so our "wonderful" postal service forwarded the license upgrade to my PObox, yet they gave me a California call....
Moving to a vanity call that indicated Hawaii was a no-brainer for me, and I'd be willing to pay 20 bucks a year to keep it, so the increase in costs still make sense to me.... I know I may get a lot of flak from some people because of this, but it's all what it's worth in my mind.... It is a hobby, and thing that are outside "standard assignment" can be expected to cost a bit more. In my mind, it would certainly be worth less than 2 bucks a month to have a call that makes sense to me in place of one that is from an area where I no longer live.

Thanks

In a lossless system sourced by monochromatic
coherent light, if the 1st medium is air and if the
index of refraction of the 3rd medium is the square of
the index of refraction of the 1/4WL 2nd medium, then
all reflections are canceled in the 1st medium. That's
one of the rules of optics for non-reflective coatings.

> How much current flows into 400.000 ohms?

Let's take a look at a simplified system. The SGCL source is
a signal generator equipped with a circulator and load resistor.
Each segment in the following 50 ohm lossless coax is 1/4WL long.

```
|--------1.25WL 50 ohm coax-------|
200W SGCL------A------B------C------D------short
```

The signal generator is sourcing 200W and the circulator load
resistor is dissipating 200W.

What is the net current at the short and at A and C?

What is the net voltage at D, B, and the source?

What is the forward power and reflected power?

What is the net current at the signal generator output?

What magnitude of current is the signal generator sourcing?

What magnitude of current is flowing through the circulator
load resistor?

What is the phase difference between the forward current and
reflected current?

Probably not a bad idea really! On the previous truck I had, It was a lot of
messing around to figure out where the hole should be made and I did a so so
job of the hole with of all things a paddle bit. The cable did route easily
though. That might not be the case this time! Since they do it all the time
they would know just where the best place to make the hole is.

Better than just steel wool- is SOS pads- had Deer Mice (carriers of hantavirus) running between buildings, in wire ducts- plugged with SOS pads, stopped them. Also had professional folks, that used a gooey substance, that (according to them !) tastes bad to rodents for treating wood, so they didn't like to chew thru walls. Apparently the bad taste of the soap, and the goo, along with the steel wool does a good job of slowing them down-- It is a bit disconcerting to open the control head of a generator, and see 8-9 pairs of eyeballs stareing back at you! Jim NN7K

4275. New Program. L-match Networks.

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-14 09:02:59 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <ddn1c3$ne1$1@nwrdmz03.dmz.ncs.ea.ibs-infra.bt.com>
Source record: 71843

Occasionally it may be useful to deduce the value of the terminating impedance of an L-match network when only the values of the coil (uH) and capacitor (pF) and the frequency are known.

Program L_NETWK does exactly that.

The terminating impedance is often the input impedance of the transmission line leading to an antenna when an impedance measuring device is not available. Whereas it is possible to estimate the values of the coil and capacitor settings from a visual examination. The L and C components having been set by using the SWR meter or TLI.

The program also assists with assessing the range of terminating impedances which can be accomodated by a given L-tuner. Without such assistance a considerable strain is placed on an ordinary person's imagination.

Download in a few seconds program L_NETWK from the website below and run immediately. No unzipping inconvenience.

Given an ideal system with carefully selected boundary conditions,
all reflections are canceled. That is a concept, not something
that can be achieved in reality. Your height and weight on your
driver's license is not 100% accurate either but it is good
enough for government work.

Regarding steel wool, I recall an old old radio catalog selling an antenna cleaning kit to shine up your antenna wire -- claims it improved reception !

Don't recall if it was steel wool or a fine sandpaper

But when you put up a brand new shiny antenna -- does it seem to work better, just like your car runs better after a wash and wax job (;-)

--
CL -- I doubt, therefore I might be !

Well, they're not. But you have to dig them out of the dashboards
of automobiles and rig up 12VDC power supplies for'em.

Sure, but it involves locating two 250 Watt, non-inductive resistors --
one of 25 ohm and one of 50 ohm. Hard to find. Pricey.

You could use the resistors.
But if you still want the antenna to preform correctly, do the
following.

For 500 watt (FM only; 52-54 MHz) capability,
contact Diamond Customer Service at (760) 744-0900 for further
information.

Interesting, Fred, I wasn't aware that the 3B24 was a gas-filled rectifier. However, I used the 80, the 81 (a half-wave rectifier with greater current capability than the 80), the 83 (a full-wave mercury vapor rectifier) The 5Y3 was a later version of the 80, with octal pin basing. I also used a whole bunch of 866's before SSB came along. They powered a 203-A in one of my early rigs, a 250-TH in a later rig in 1935, and a pair of HK-54's in another in 1937. (Or were they HK-354's, I can't remember, yeah, 354's)

I can't belive no one has put up the correct answer. When grid leak becomes
a problem, adding a dynatron oscillator, with it's negative resistance
absorbs all the leaked electrons.

New question:

A Homotron is -
a. An electron that has been given a positive charge
b. An electron given a negative charge
c. A queer electron that blows fuses
d. Who knows, it wasn't in the list of questions I memorized.

One way to do this is fairly simple. wind a flat coil. Take a piece of hard paper or cardboard and cut it into aabout a 6 inch circle. Cut notches all along the outer edge. Now wind about 20 turns of small wire through these outer edge notches. Place it on the bottom of your cupboard just above your radio. Attach an antenna (the best you can manage) to one terminal and your water pipe ground to the other terminal. This will do wonders for reception. You can still stack dishes on top of it. It is a shame that sensitive am radios are so rare these days.

Bart:

I strongly suspect you are correct and, either the dielectric and/or construction/spacing of the cap plates, etc, is not sufficient to handle the rf voltage/current though it.

Less likely would be the insulation/gauge of the inductor is not sufficent, or its' spacing away from other components is insufficient.

Never hurts to consult all sources though...

A Thrashed Ham.

Sending morse code with a signal light is faster than signal flags,
especially at night.

My National NC-54, i think, had the same design feature! :-)

Sensitivity on 10 meters was, well different. I could hear W1VUO and W1GID with excellent Q5 copy. I could never hear who they were working!

I figured out that it must be my receiver. After all, W1GID lived 200 yards North and W1VOU lived 1/2 mile west. Never heard anything else on 10 meters until I bought a REAL radio, HQ-140X.

BTW, in Boy Scouts I did build a Regenerative for 6 meters. It earned a Worked All TV sets award :-) Channel 2 is/was a major supplier in the Boston TV market.

Depends. A couple of years ago I was doing some messy sheetrock work
and was wearing an old pair of shorts. When I finished for the day I
threw them on the floor and took my shower. The next morning I
slipped them back on, when out to the kitchen and got a cup of Joe and
sat down in front of the computer to read r.r.a.a.

I was sitting here when I felt a scratching on my leg. I jumped up
and exited the shorts in record time. Sure enough, there was a bark
scorpion in my drawers. We have three species here and of course the
most dangerous is the bark scorpion and they are the ones that most
like living in houses. I smacked that one with a handy book. To stay
on topic, let me say that it was probably the ARRL Antenna Book. :-)

Otherwise, it's whatever shoe is handy.

He speaks the truth -- I remember that one also.

The passing score on those tests was 75%, but you only had to know the answers to 50% in order to pass. There were four choices to each question; two were of the quality of the one Jim quotes. So if you answered the half you knew, you had a 50-50 chance with the rest of them by throwing out the ridiculous answers and random guessing between the two that remained. (Actually, you could do better yet with even less real knowledge by using a little basic testmanship.)

Do not remember that question on my exam in the 50s. Do remember much huffing and puffing about the quality of the schematics that I had to draw and questions about B modulation (spark). Had to go to Detroit to take the exam. Entirely different city now.

But then, you may have taken the exam before I did. Fortunately, licenses in those days did not have age information on them. Had a job with a radio station when I was underage - the owner, also a Scot, knew not to ask and I knew not to tell. Still can smell the mice that got RF burned in the ammeter shunts. Some of us are getting on......

That is very true, but most people won't go to that kind of trouble. I have a Honda radio I pulled out of my 98 CRV. It is the most sensitive am radio I have ever seen. I am setting it up in my shop with an antenna because I live 54 miles from the nearest town. It pulls in stations a couple of hundred miles away in the daytime. I replaced it with an mp3 player. I really like my own music on a trip.

I'm running an FT-8800 for voice with a Comet CA-2x4SR on a trunk lid
mount and run APRS with a 20W brick amp into a Hustler 5/8 on a hood
lip mount. De- sense yes, damage not so far. I also have a dual band
scanner antenna on the opposite side of the trunk lid and the FT-8800
nor the 75W V-8000 before it have hurt the scanner. Other radios may
not be as tolerant of the overload.

Walt I went back through some old note books, according to my records I sent the letter to the editor in 1977. I know Roy says 93, but I have e-mails from that period and knew it had to be earlier.

Does that match your recollection?

My mother had to drive me to my first day on the job as a broadcast engineer -- I wasn't old enough to get a driver's license or, in the state I was in, even a learner's permit. (I did know how to drive, though, having gotten a learner's permit in Alaska at 14. Drove quite a bit of the way down the Alaska highway, too, unpaved at the time.) I'd been turned down for a job as a golf caddie because I wasn't old enough. That was 1961.

The owner of that first station I worked for became a fugitive from a felony conviction in about 1964. Don't think they ever caught him.

Source record: 71783

I assume this is a ground mount? In that case, measuring
the length of the radials is generally a waste of time.
Cutting them to resonance is not needed, unless they are
elevated. The most ground loss is directly at the base of
the antenna. So many short radials are better than a few
long ones. How tall is the vertical? If me, I would probably
run radials the same appx length of the antenna if I had a lot
of wire. But if limited wire, I would cut them shorter, and use
more of them. Only with elevated radials , do they need to be
resonant. Any radials on the ground will be detuned by the
ground. As far as the question, seems to me they would be
appx equal. The trimmed radials might be slightly better.
But not cuz they are tuned...Cuz, 4x9 bands =36 radials.
That would be slightly more wire at the base, than the 32
untrimmed radials... :/ And some would be longer than 24 ft... MK

The more radials the better. Many suggest that after 60 radials one hits the point of diminishing return. I have 72 on my Hustler 5-BTV and it really does make a huge difference. Mine add up to about 1300 ft of wire total. Photos of the entire installation at...

I still can't believe anyone took this seriously.
Steel wool must have slightly higher permeability than air, certainly no
match for ferrites.

Dear Roy:
Outstanding. What a shame that that route for young people is closed.
I was able to ride a bicycle to the station. Would buy a quart of milk
on my way to the station from a delivery van and have a simple breakfast
while playing some sort of public service announcement to start the
broadcast day. My Mother had to cash my checks for me because I was working
when the bank was open. Very interesting people pass through broadcast
stations. Another form of early education.
Obviously, we both looked older than we were. Many years latter, I
learned that I had been chosen over other (smarter?) candidates for some
important opportunities because of the experience and initiative shown by
working as a broadcast "engineer." How do young people today demonstrate
such characteristics?

Let's face it, Morse had an important need at one time in the history of radio. As a result, many amateur spent countless hours perfecting this craft. I'm glad they did.

However, technology has advanced (thank God) to a point where Morse is all but obsolete. My hope is that when the FCC removes the Morse requirement, more amateurs will spend that time improving their technical abilities.

The nice thing about amateur radio is that it flexible and offers many (very necessary) opportunities to its ranks.
I believe the Morse requirement just distracts people from other more exciting (and more necessary) aspect of the hobby.

4325. Short 80m antenna, suggestions??

Newsgroup: rec.radio.amateur.antenna

I haven't got the room for a good 80m antenna. My vertical covers 40 so no trouble there. I am looking for ideas on a short 80m that will give half decent results. I have about 66' available straight or can make some kind of inverted vee ???

I'm not the person being questioned above but I took shop class in High
School. Passed with flying colors. Does that count?

Source record: 71796

If you have done nothing interesting in the last day, week, month or year which is of any interest to most, you just might be an old timer.

If your newest equipment is over a decade old, you just might be an old timer.

If 40 and younger avoid you on the nets, you just might be an old timer.

If you can't crawl the tower anymore, pullup the mast, you just might be an old timer.

If your next stop is the resthome where your radio will be denied you, you just might be a old timer.

If you live in the past and think the bands are over crowded, you just might be an old timer.

If most of your exchanges and communications with others ends up into a sermon from you, a list of everything which is wrong, constant references to the past, and an attempt to stop progress, you might be an old timer.

If you can't see how horrible the above is, you might be an old timer.

My suggestion: Use the 102 ft G5RV length and let 18 ft. hang down
on each end. Feed it with ~23 ft of 450 ohm ladder-line. Put a
parallel cap of ~1000 pf across the ladder-line at the ladder-line
to coax junction on the antenna side of the choke. You probably won't
even need a tuner for the resonant frequency.

My second choice would be to go with the 66 ft. total length with
high-Q loading coils in the center of each 33 ft. leg.

Put up 66 ft of wire, or any length that is convenient. Wire length is unimportant. Inverted vee is ok. Feed it with open wire line (Or 450 ohm ladder line) an any point you like. It will work just the same as a full sized dipole. Do not use any coax in the feedline, losses can be very high, even with very short lengths. You do need a well designed tuner, with low losses. Fairly high voltages will be present at the output of the tuner.

Regards.

Frank

As an example on 3.8 MHz: 66 ft of #14 AWG wire, fed in the center, 30 ft high above average ground Er = 13 Sigma = 5 mS/m. Radiation efficiency 96%. Fed with 50 ft of 600 ohm open wire line: input impedance = 748 + j2087 maximum voltage at feedpoint, with 1.5 kW input, 3.05 kV. Series C, shunt L tuner, with inductor loaded Q of 200. Tuner Loss = 0.24 dB.

Forgot to mention. The transmission line loss is about 0.2 dB.

I have an R7 up for 40-10. Two maple trees on the property, one in the front yard and one in the back but not far enough apart for an 80m dipole. The trees runs east west over the house. I would prefer to run the dipole north south, using the backyard maple for a support. The lot at this point is 66' wide. One other thing to mention I don't think I can run ladder line or open wire feeder into the house. I am pretty much limited to coax.

Thanks for the help,

Max

EZNEC says that a 66 ft dipole used on 3.8 MHz, fed with 450 ohm
ladder-line, will have an SWR of greater than 100:1. This can
lead to all sorts of undesirable effects including an almost
impossible to match impedance at the tuner. A practical rule of
thumb might be in order, e.g. mine = no more than 20:1 SWR on the
ladder-line.

I am soon to inherit my mothers house If I can stay alive longer
than she does with her cancer and me with my heart trubs'
Anyhow, if anyone knows... there are currently no
covenants about antennas for this neighborhood.. Wheew!
I got a copy from the deeds place to be safe and
the covenants expire in 5 more years. 35 yrs from dated
land sub-division development.

Question is what happens after the covenants expire?

Can someone write and file new ones?
Will they have to allow me time etc do file protests or what ever?
If I get my antennas up first do they have to be "grandfathered"
into any new covenants?

I don't plan huge or "obscene" type antennas, just
something to get on the air again with. Maybe a
short stout tower to get over the top of the roof.
Might be a vertical or two in the future 2m. 10m?
But I am still stuck with these nagging questions in
today's environment.

Thanks anyone K4TWO Gary

I guess my question wasn't clear, Max.

Even though your space is limited, the type of antenna you install should be informed if possible by the type of operating you intend to do. If DX is very important to you (and here, DX could mean one or two thousand miles) you might want to work in some vertically polarized radiation, such as with an inverted L or a T (vertical with capacitive element on top) or a sloper. How tall are those maple trees?

It may even be possible to load the R7 on 80 with a switched loading coil at the base. Wouldn't win any efficiency awards I'm sure. But thinking about it is pretty cheap and even fun.

I just got done building a "shortened" 75M dipole for traveling. It is 27' on each leg. Homemade coils are out from the apex 15'. Doing a little research in some old antenna books, and on web, I found good, easy, information on calculating the value of the coils, depending on how far out from the apex you want. In my case, I needed 50uH coils, which I wound on some 1.5 inch plastic pluming material with #22 close spaced telephone house wiring. For my little 5W FT-817 this works quite well, but if you are running more power, you'll need to build a bit more robust coil. Apex is held up with one of those 23' RV telescoping fibreglass flag masts.

While open ladder line feed would give you a lot more flexibility, if you must use coax, then what I did sure would be an easy thing to do. If you need coil computation data and can't find it yourself, email me and I will try to get it to you.

Hi Norm, I have never installed an MFJ 1777, but have installed dozens of antennas just like it. The antenna is a 102' doublet fed with 450 ohm ladder line. The MFJ manual says it has to be used with a balanced antenna tuner. A new or used balanced antenna tuner will cost 3-4 times the $50 price tag for the antenna. The antenna will have to be used with some type of tuner, a "T" type will work, or a simple "L" network, with a suitable balun.
As far as installing, hang it high enough so the transmission line just gets to the tuner, that would be optimum.
If you want to use it on 160M that will require reconfiguring the antenna, not that difficult, but still a pain.

I would strongly encourage you to get advice from a local lawyer who
understands your state and local housing laws. There seems to be
quite a bit of variation from one area of the country to another, and
it's likely that advice you might be given might not apply in your area.

In some areas, the local homeowner's association is granted quite a
bit of power to create new covenants. This can be done by the HO's
board, which may or may not have been elected by a majority of the
homeowners, and their actions may or may not be subject to review by
the homeowners.

>But I am still stuck with these nagging questions in
>today's environment.

If you want answers that you can depend upon, I think you ought to
plan to speak with a lawyer who practices property law in the county
in which the home exists.

> ladder-line.

Fact is Cecil I never pay any attention to VSWR, just complex numbers.
Anyway your comments made me re-analyze the problem, and I realize I made an
error in the transmission line and antenna tuner analysis. I thought the
transmission line loss I came up with was a bit low. The final numbers are
shown below. See if you agree with me; then explain where I went wrong, and
why the match will not work.

66 ft dipole, 30 ft high, #14 AWG: Input Z = 11.3 - j961 ohms.
50 ft of 600 ohm line: Input Z = 5.48 + j189.85 ohms, loss = 1.95 dB
Matching network: Shunt C = 296 pF, Series L = 22.8 uH.
(Obviously half the L for each side of a balanced.line.)
Max line voltage: 1.5 kW in = 3 kV.
Tuner loss: 0.44 dB.

Incidentally have you ever looked at a typical airport NDB site? For
example a 45 ft monopole on 350 kHz has an input impedance of 0.2 - j7054,
which is a VSWR of 4.9 million : 1 -- whatever that means -- virtually
touching the edge of the Smith Chart. I have even seen 5 mile approach NDBs
with 30 ft monopoles. Marine installations for 400 to 500 kHz operation
frequently had electrically very small inverted "L" antennas. Of course 5
S/m sure helped, but the losses in the tuners must have been significant.

73,

Frank

The maple trees are pretty tall, getting up in there high enough would be a challenge. I may try 66' per side and see how high in the tree I have to go to get the angle out to the corners of the lot. Would a direct feed with 50 ohm coax be suitable with a choke balun? Mainly interested in local comms out to 3 or 400 miles.

Max, is that to mean you want to feed the 66' dipole with 50 ohm coax
(all the way from the rig to the centre of the dipole)?

Assuming the feedpoint impedance that others have modelled is about
right, and that was 11-j961 at 3.8MHz... the losses in 20m (60') of
RG213 would be around 18dB. That is, less than 2% of the power into
the cable reaches the feedpoint.

That isn't the end of the story, there will be tuner losses... but the
good news is that partly as a result of the very high coax losses, the
impedance presented to the tuner will be well within the range of
loads that can be transformed at fairly low loss.

So... less than 2% of the transmitter power reaching the feedpoint...
is that acceptable?

BTW, if you considered a shorter line, say half the length at 10m (or
30'), the losses would be around 13dB (note considerably more than
half of the losses for 20m of line - the loss/unit-length is not
constant along the line).

It turns out that in practice, it is very hard to get most of the
transmitter power to the feedpoint of a dipole when the dipole length
gets much below 35% of the wavelength. Using lossy feedline (like
coax) exacerbates the problem.

Owen

Back around 1962, I was working on the Syncom satellite program at Hughes Aircraft. NASA wanted us to make some satellite transponder simulators so they could check out the ground stations. The plan was to take some of the 'less than perfect' hardware and package it up in a metal box. Unfortunately a lot of that stuff wasn't very stable, particularly the varactor multipliers. To make things worse, they used TWT amplifiers (in a separate box) followed by a 10 watt attenuator which brought the output back down to about the same level as the drive to the TWT. We ended up lining the boxes with steel wool along with a lot of metal tape to seal the seams, etc., and it did seem to help (a bit).

I remember the steel-wool balun story and wondered at the time if perhaps it was merely absorbing some of the current on the outside of the coax.

The filter in that unit was a
Gilette double-edged type.

I remember one that could slice a QSO right in half,
with just a knock of the leg against the table. :(
Once kicked, I'd usually never find them again.
Not the most mechanically stable thing I ever saw, but
that was in jr.hi, and we used what we had...
Luckily, it was not my radio. :/ My first novice rcvr was
a hammarlund HQ-110...Not quite as kickable.
He later got a SX-40? that was half decent...You couldn't
kick a guy off freq with it.. :/ I've got an old national here
that looks about like a S-38...Someone gave it to me
years ago, and to this day, I've never tried to use it, or
plug it in... :/ I think it's cuz it reminds me of that S-38...

You can try bending the ends to fit in the space you have...something
like "[" ought to work (top view--fed at the center, dipole). Or, if
you want to make loading coils, you can find the values you need in the
ARRL Antenna Book in the chapter on limited space antennas.

I'm in a condo, which is also somewhat restrictive in terms of radio antennas and transmitters. Don't get discouraged, there are ways around it. Best thing to do is to look into QRP operation (power levels 5w and lower). I'm using an FT-817 which won't do any more than that, and a somewhat stealthily-arranged shorty G5RV antenna for 40m thru 10m, and a 2m vertical up where an old busted-up TV antenna used to be when we moved in. With that arrangement, I can work all the 2m repeaters in the area, and on HF I've worked all over the country plus several countries around the Pacific and into South America. Never had a TVI complaint at all.

One thing I =did= do was put the antenna up first, and leave it up for a couple of months before I did any transmitting. I read about one guy who had a neighbor start complaining immediately after he saw the antenna the guy put up. Since the antenna wasn't even connected to anything, the neighbor was caught without an explanation or complaint about the ham. Fortunately, nobody came by and started complaining so I proceeded with getting on the air, still no interference complaints and I've been operating for something like seven years now.

Another good story was a ham who was sitting in his living room watching the tube -- no radios on in the shack at all -- when a neighbor came by, furious because he was getting TV interference, and was POSITIVE it was the fault of this ham. The ham said, let's go see, so they went to the neighbor's house to look. Sure enough, there was a lot of TVI. The neighbor said, see, you're screwing up my TV! The ham said, how can that be? I'm standing right here, no radio in sight, so how can I be messing up your TV...?

Anyway, consider QRP -- you will be surprised at how much you can accomplish on only five watts!

I failed to notice you did not want to use open wire line. If you use inductive loading, for example: nominal 46 uH, Q = 200, at 15 ft from each end of a 66 ft dipole. The radiation efficiency is 71%, i.e you loose 1.5 dB in the loading coils. The input impedance is 28 ohms, and the losses on 60 ft of RG213 will only be 0.24 dB. Orientation of the dipole is unimportant since at 30 ft high the radiation is essentially omni-directional.

73,

Frank

Hi Frank,

Unfortunately using open-wire is not an option, as I have to feed the
feedline in through the exterior brick wall of the house. I have 2 feedlines
running out now. One to the R7 and the other for experimenting. I am going
to try your suggestions with the loading coils, as soon as I get back from
vacation!!

hi,

There is a topic on www.eham.net for
antenna restrictions in the forums section.

Lots of good ideas there but best to
check with the local lawyers.

Good thing is perhaps everyone has
forgotten about these restrictions if any.

Good luck with your health issues.

Everything appears quiet on the Western Front. So let's waken things up.

Is there anybody about who still imagines that an SWR meter, located in the transmitter, or even on the other side of the tuner, indicates SWR on the transmission line between transmitter and the antenna?

Reg, G4FGQ

4367. Homebrew HT antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-16 16:19:27 UTC
From: Ken Bessler <kg0wx@NOSPAMyahoo.com>
Message-ID: <jmoMe.2446$ct5.1920@fed1read04>
Source record: 71735

I just built a 1/4 wave (146mhz) antenna for my dual band
HT (Yaesu FT-51r). It's simply 19.25" of .025" piano wire
soldered into the core of a broken SO-239/BNC adapter.
The BNC center pin just sits in the socket in the radio with
a rubber bnc cap keeping the antenna load off the pin and
keeping dirt out. It's all a press fit and it seems to work great.

Comparing it to my OEM rubber duck, it's about 2-4 S units
better on 2m & 440. As I understand it, it works as a 3/4
wave antenna on UHF and should be a good match but the
radiation angle won't be perfect.

My question is this: What would be the radiation angle on 440?

I know I'm picking nits here but I'm interested in the theroy.

P.S. The FT-51R is an all metal case HT which should provide
a good capacitive couple to my hand but what about when
the HT is on the back of my backpack? What counterpoise do
I get then? Maybe from the mic cable?

If it's a stand-alone SWR meter with three foot 50 ohm
coax cables on the input and output, then it is located
in a 50 ohm environment and is indeed indicating the correct
SWR. The thing that makes an SWR meter indicate a valid value
is if its physical environment is extensive enough to force
the impedance ratio of Vfor/Ifor = Vref/Iref = 50 ohms.

Back when I got my first license, those things were called
transmatches. Seems you would like that name better than
SWR meter. TRANSmitter MATCHing device = Transmatch.

The EZNEC program can be used to model the antenna which you constructed and show you the expected radiation pattern.

From playing with 3/4 wave antennas in the past, I would expect lobes to form which pushed the radiation angle towards the sky--where few HT exists.

Hello again Walt, I trust you are well.

I wouldn't go so far as listing them as morons. Just unfortunates who have been afflicted by the plagiarist outpourings of old wives who are still in the 1950's

A long thread is not expected. People are reluctant to admit past beliefs. I was just testing the present situation. But you never can tell, people may write in just to disprove my expectations. There's much to be learned in addition to mere SWR.

Yours, Reg.

Cecil your argument begins with a big "If".

If only pigs could fly!

Nevertherless I agree with your name Transmatch. As you already know,
I myself advocate renaming the SWR meter as a TLI - Transmitter
Loading Indicator - which is what it actually is.

By no stretch of the imagination is it a Standing Wave Meter.

Reg.

It's just about impossible to say. Your body is radiating at least as much as the "antenna", and the pattern is determined the combination.

> I know I'm picking nits here but I'm interested in the theroy.

The theory says that if you put any current I into the antenna, an equal current I flows from the inside of the antenna connector shell over the edge, over the HT case, and into any conductor it can find. The amount of radiation from the antenna is proportional to the current on each part of the antenna multiplied by the length of wire it flows on. The radiation from the HT case or your body is proportion to the current on each part of it multiplied by the length of the conductor it flows on. Your body and the HT case follow the same rules as the "antenna", and are at least as important a part of the radiating system. The overall pattern is the sum of the fields from all those current-conductor length products, from both the "antenna" and your body.

>

> the HT is on the back of my backpack? What counterpoise do
> I get then? Maybe from the mic cable?

Yes, the mic cable and case will become the other half of the antenna system. If you unplug the mic, the current into the "antenna" will drop (on 2 meters at least) because the impedance of the outside of the case will be relatively high because of its short length. And only the amount of current that flows on the outside of the case will flow into the "antenna".

An SWR meter is no different from any other piece of
measuring equipment. One shouldn't use a DC ohm-meter
to measure RF impedance. One shouldn't use an SWR meter
designed for a Z0=50 ohm environment in an environment
where Z0 is unknown or non-existant.

Earlier, I didn't mean to imply that the SWR meter was
known as a Transmatch. It was the entire antenna tuner
that was (and still is) known as a Transmatch.

Why is there a formula to quantify reflected power from an SWR reading? I have been using SWR meters all my life to check on reflected power from the antenna. This simple act has worked very very well for me through the years. I did this in my younger days professionaly for Raytheon. When I had tuned the antenna tuner or the antenna itself for a 1:1 match, suddenly I have a system that talks a long way. What was wrong with that?

Reg,

Instead of yet another posting on the topic beyond the 20 or so you've already blessed us with proposing the new TLA (three letter acronym) of TLI, why don't you start by contacting Agilent (formerly HP), Narda, Anritsu, and the other manufacturers of precision terminators? Surely those professionals will see the impeccable logic of your proposal, and will immediately cease publishing a maximum SWR specification for their terminators. Then the manufacturers of RF transistors, directional couplers, attenuators, and other RF devices, which now have input SWR specifications, will follow. Of course, they can't call the former SWR the TLI, since it's not indicating anything, and there's not necessarily a transmitter involved. And the whole object here is to be consistent and rational, after all. So how about "RER" for "Reg Edwards Ratio", as in "guaranteed maximum RER = 1.1"? No one should confuse that with anything else.

Wouldn't this be a wonderful world (AWW) if only we were always strictly logical (ASL)?

Can you get something through a window? If the window can be opened,
you can place plexiglas or wood in the window, and then cut the
appropriate openings for ladder line.

================================

Bob,

To follow that American tennis player : "You can't be serious!
!!&$***!!! "

If initially it's inside the transmitter then on the other side of the
tuner implies it's on the other side of the tuner from the
transmitter.

Unless, of course, it's mounted in the 115V power lead TO the
transmitter.

Now can you comment? ;o)

Gee thanks. Read many. Now may have to move to another planet.

No wonder some folks go nuts. The same folks that b--ch and complain
would be the first to beg for help in an emergency eh.

Now I know why all the blacksmith shops in the westerns were on the end
of town.... covenants ran em off.

I wonder how covenants come in to play if I get a good size motor home or
RV and hang a humongous antenna and crank up on it.... mobile radio. Maybe
with some directive antennas I could squirt at the complainers homes. LOL

Good luck everyone. I'll put mine up and take a chance no one notices with
the trees in the background and the motorcycle/motorboat boob next door
Just the individual not the groups. varooooom!!!

Need more information: How high is the antenna, what type of transmission line do you plan on using, and what frequencies will it be used on?

Bending the antenna will reduce the real part of the input impedance, thus increasing transmission line losses. It will also tend to increase its directivity in the direction of the "vee".

The G5RV antenna tends to exhibit higher transmission line losses. See the extensive analysis at www.vk1od.net

Suggest you obtain the free download of EZNEC from www.eznec.com then you can analyze the antenna for yourself. Also there are many free programs available for transmission line analysis. Probably Reg (G4FGQ) has one for free.

Regards,

Frank (VE6CB)

Reg, if he really doesn't like you, he will "ploink" you,
akin to being shunned by your religious sect (a fate worse
than death). :-) If you do succeed in getting "ploinked",
you can join our prestigious club (but not before). What
I did to get "ploinked" was to say that an antenna is a
"distributed network", not a "lumped circuit". Who knows,
maybe that would work for you also to get "ploinked"?

Cecil:

You know, that wasn't right, I just passed that off with such a "frivolous air."

It is a shame to see one erect him/herself as a "God", intolerant, commanding and shoving a stone tablet into your hands. Removing themselves to a "throne" which none can visit (debate, argument, learning) except if commanded (allowed?) to do so.

(must make it difficult to sit down, for the "God" I mean, attempting to take a seat with multiple lips stuck to yer bottom! Poor bugger! <grin>)

What causes this to occur I really can only guess at, best guess is blinded by the light of their own ego, but may affect the elderly more-so than other groups, we all need to be aware, we will all be there...

I understand and pity them, have seen the same within my immediate family... <frown>

Sorry, but amateur radio is meant to be a hobby (at least one use of it is!), I don't think it is a crime to have a bit of fun either. Amateur radio assuming a "pseudo-military" air ruins its' use to many and attracts far too many with a rigid, disciplinarian and warrior mentality...

And, sorry again, I see newsgroups as a "social cocktail party", or a "town hall meeting", not a church where you worship gods and get a sermon by a priest... of course, my demeanor here has all ready given that away--most likely... I like the complex and intricate here--your arguments along with richards' and others are appreciated (you cause me to dig out my programmable calculator and follow along), and the practical is much appreciated too, even the "unconventional" challenging the accepted is/are good for brain food...

4409. Indoor AM Radio Extension

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-18 01:44:32 UTC
From: ECJ <ECJoyce@gmail.com>
Message-ID: <1124329472.084693.265940@g43g2000cwa.googlegroups.com>
Source record: 71677

My radio is in the middle of a building out in the country and I can't seem to pick up am radio. To solve this problem I tried using speaker wire to extend it approximately 25 feet to the window in the office next door reconnecting it to the loop antenna that came with the radio. I had no luck. Is speaker wire an effective way to extend an AM antenna? If so what would be the best way to get better results. I thought maybe tinning the end of the speaker cable that goes into the radio , as well as soldering the speaker wire directly to the am antenna instead of just wrapping it might help. Any suggestions are appreciated.

ECJ

4410. Re: Indoor AM Radio Extension

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-18 02:14:28 UTC
From: John Smith <assemblywizard@gmail.com>
Message-ID: <pan.2005.08.18.02.14.25.674618@gmail.com>
Source record: 71678

ECJ:

Wind ~10 turns of ~22 gauge wire on an old ferrite loopstick rod, use mini coax connected to this loopstick over to a window, if the window frame is at gnd potential, hook the braid of the coax to it (if not, look for a close gnd), take the center coax lead out, around, through the window and to a random length wire. (once I was in the middle of an office floor in a cubical, popped the coax up to ceiling tile, then across the top of the tile to the window.

Now it is only necessary to move the ferrite rod and coil (you can wrap it with electrical tape to make it secure) around the am radio case to find the internal ferrite loopstick which the one you constructed will now couple to, just tune in a weak station and move it around, you will know when you find it and have it orientated in the correct direction, tape it in place and you are good to go!

... adapt the above as necessary...

Works real good when mixed with black powder gun powder, home made
fireworks, Real colourful. Opps I think i aged myself.

Seems to me some one tried to make a capacitor with it too, if my memory is
working, again.

I've had poor luck even using the G5RV as an inverter V.

ECJ

The 25 feet of speaker wire has become a capacitor across the loop that
you re-located. That detunes the loop and produces a low impedance shunt
across the front end of the receiver.
If you are interested in one particular station, it is practical to
build/buy a tuned loop AM antenna. Google will guide you to a few
practical designs of AM loop antennas.

Hi folks, first let me apologise for not lurking, or even reading a FAQ (I did look and did not find). I know that radio amateurs are a helpful and friendly bunch, so here goes.
From the UK, for historical reasons, the BBC broadcasts programmes on Long wave, specifically 1500 metres (198 Khz???). I drive a truck on the continent of Europe, and would love to listen to this service whilst on the road (for the cricket!). I know that the signal is there, and of sufficient strength, as I can receive it OUTSIDE the truck on an ancient "portable" Inside the steel box (cab) however, too much noise/too little signal to be useful. The fitted radio has LW, but again cannot be used for the noise. Could anyone please point me to some answers to the following:
Antennae: Could I build (buy) some kind of antenna specifically to receive this emission?
(My old radio has a socket labelled "AM antenna").
Could I build a receiver tuned only to this freq., with no need for a speaker (run the sound in at headphone type power) that I could hang/bolt outside the truck (on the roof?), with its own battery and aerial? If so could someone point me to a diagram of such a beastie?

Message-ID: <11g8tur9cdvb6d7@corp.supernews.com>
Source record: 71686

Dear Mr. Stephen Parry:
It is possible that the truck (it is one truck?) produces too much noise at 198 kHz. An important test is to note if your portable radio tuned to 198 kHz receives a satisfactory signal-to-noise ratio when the truck is running all of its equipment. Try placing the portable radio next to the truck in places where one might attach an antenna.

The fitted radio, which has LW, must have an outside antenna. Is that antenna in good condition?

Your solution might be to reduce the noise produced by the truck. Antennas for LW suitable for mounting on a truck do exist, however they will not help if they receive too much noise.

Let the group know the results of your testing. Tell us more about the truck. Regards, Mac

4419. Re: G5RV in horizontal L

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-18 12:13:52 UTC
From: Jim Leder <k8cxm@spam.fuse.net>
Message-ID: <cb089$43047b7e$48317931$24325@FUSE.NET>
Source record: 71687

A G5RV is really an inefficient collinear antenna, so it needs to be a flatop, not a Vee or L. Model it and you will see it is a 'long' (on 20 meters) Extended Double Zepp. The extra length improves the pattern into multiple lobes at the cost of some gain. A true EDZ has more gain, but only one very narrow broadside lobe off each side. The G5RV has 3 lobes off each side.

I predict it will change the pattern, change the input impedance and probably otherwise work well. Sometimes you have to get along with what you have rather than what you want. Modern rigs like to see 50 ohms, so plan on using something to match your transmission line and go for it.

Is the noise coming out of the radio speaker or is
it the physical noise level that is the problem?

Jim, your statement is a little confusing. I know you mean that the
G5RV is 1/4WL too long to be called an Extended Double Zepp on 20m.
An EDZ is a single frequency antenna. The 102' G5RV is an EDZ on 11.5
MHz. EDZ length = 1170/F. And, you're right, G5RV's perform better as
a flat-top.

My modified G5RV performs as well as my 130' doublet fed with ladder-
line, given the slightly different radiation patterns. I vary the
length of the G5RV series matching section as follows:

3.8 MHz 23 ft., 7.2 MHz 35 ft., 10.125 MHz 20 ft., 14.2 Mhz 29 ft.,
18.14 Mhz 36 ft., 21.3 MHz 27 ft., 24.95 MHz 29 ft., 28.4 Mhz 22.5 ft.

Stephen Parry wrote:
"I drive a truck on the continent of Europe, and would love to listen to this service on the road for cricket."

The Blau Punkt in my Karman Ghia got such signals all over the continent, and I`m just one of millions.

Mr Parry did not say if his truck is Diesel powered as most European trucks are. If so, he is free of his own ignition noise, usually the hardest to suppress. He still may have alternator whine (perhaps a bad diode) and he may have static discharges from things which rotate. Some are under the hood, and their radiation should be kept under the hood by the metal surrounding them. All such metal pieces should be bonded together to keep the trap they form closed.

All conductors coming through or under the firewall should be well grounded or bypassed with capacitors at the firewall. The exhausr pipe may need bonding here also.

Maybe there is a gasoline powered rerfrigeration compressor generating ignition noise. Standard resistance wires, capacitors, and bondibg should silence that.

Springs can be used in wheel hubs to ground out static.

All the metal parts of the truck may have to be bonded together.

My Blau Punkt was equipped with a good sized choke coil in its battery lead. It also had an internal "spark-plate" capacitor, and these rid the power source of radio noise.

The telescoping antenna (about 50 years ago) could be extended to about 100 inches, which made the Karman Ghia quite a sight, but it worked. The antenna cable was the standard high-impedance small inner-wire coaxial type. This must be intact and perfect to keep the signal on track and the noise out. Though German, it used Motorola connectors.

Radio frequencies decline very rapidly near their source. This is your friend when the source causes interference. Keep the antenna away from and shielded from sources of interferebce.

In 1935, Alfred A, Ghirardi (E.E.) wrote:
"---an aerial must be installed in (or on) the roof, under the running boards or chassis of the car, or in some other locations.
---Considerable attention must be given to the ignition and other electrical wiring of the car in order to eliminate all electrical interference which it produces in the receiver."

Noise problems are more often caused by the vehicle than by the receiver but some receivers may not be shielded and filtered well enough. If the truck cab has its pieces bonded together and all pass-through conductors are well bonded or bypassed, it should be electrically quiet. You should be able to use a portable radio in there with proper placement or an outside antenna.

Ghirardi devotes an entire chapter to automobile radio installation in "Modern Radio Servicing". Car radios are hot in the summer months while home radios are not.

Best regards, Richard Harrison, KB5WZI

One problem you might look at aside from all the other great suggestions is to look at how your radio voltage is derived. Most trucks are 24 volt and the radios 12 volt.

Are you tapping at the junction of the two twelve volt batteries or does your truck use a 24 to 12 volt converter? These are usually really noisy from an electrical standpoint.

Even worse John is what men have been turned into.

Check out the "sensitive" Bounty towel guy. If he wouldn't suck a dick,
surly he would hold it in his mouth until the swelling went down.

Men have fallen for the bull crap that women want a sensitive guy, when they
really want a dangerous guy.

The little blonde girl shuns the sensitive guy she says she wants and hooks
up with the dangerous ghetto crack head.

Fred:

Having a "blatantly honest day" today, are we?

But yes, I can agree in spirit with most of that, human psychology in a
sane mind is a trip, toss in a bit of "high-strangeness" and things really
get weird.

John

Fred, W4JLE raised a number of intresting points. DC to DC converters are switching types to get high efficiency and this can generate many harmonics. If not suppressed, as many converters are, this causes much noise. The solution is to use the proper converter if required.

Yes England can be well received all over the European continent. The transmissions are powerful and decline only about 6 dB every time distance from the transmitter is doubled after the first 1.5 km from the 200 KHz transmitter.

The questioner referred to his truck cab as a "steel box". I accept his word. However, I once had a Corvette with a fiberglass body. The ignition system came well shielded and bypassed. The underside of the hood was equipped with a fibergaass blanket for heat control and the blanket was faced with aluminum foil for radio frequency control. It was grounded. Trucks must use something similar if they have spark ignition systems.

The Corvette`s Delco radio only had medium wave AM and VHF FM reception. Both were satisfactorily quiet. Screams during acceleration and sudden stops were the only disconcerting noises.

Having said that it's a poor inverted V, it does a great job as a flat top.
I've worked quite a bit of DX on 75 and 40 with my G5RV at 20'.

Richard, I don't know anyone working in the technical area of radio transmission ever earning enough to enjoy a Corvette. Did you have a large inheritance?

No big windfall. I worked in Europe on a good salery for years. After the first two, all I had to do was stay away rrom the U.S.A. and my salery was tax-free. Then I investerd for the long term in some unspectacular stocks with rising earmimgs and stock ptices. For fun I bought some hot short term stocks too. I won some and I lost some, but you only have to make one killing to pay for the losses. Diversification is the key to staying in the game. Timing the market is highly unlikely. So is reliable information unless it is first-hand.

I could tell you that Motorola is cash-rich and is buying back anout 10% of its stock, but the Galvins are gone (except for Christopher) so the stock is questionable. The management must think the stock is a good investment or they shouldn`t be buying it. Who knows?

Best regards, Richard Harrison, KB5WZI

California women _are_ far better looking than the rest. It may be
because many of them refrain from eating too much. Most of them are
superior in any event.

Beauty is in the eye of the beholder.

The skinny woman reminds me of Louis Prima`s selection from Capitol Records T836, "Call of the Wildest". The selection is "Closest to the Bone". We had Louis Prima V-Disks aboard our ship during WW-2. They were about the most popular of all our disks. With today`s "correctness" Louis would be relegated to V-Disks or Vegas. He was a huge hit in both places.

In Louie`s lyric, "the nearer the bone, the sweeter the meat. When his sweetie drinks a glass of wine, she looks just like a thermometer", and other crazy stuff. Louis Prima was one of a kind. We could use some of his fun and musicianship today. His Cornet would compete with Louis Armstrong or Harry James. His orchestra could compete too. Sam Butera`s Saxophone was competition for Tex Beneke. Too bad the great music and entertainers are almost gone.

Back in the day, when I was a young navy officer, I had my share of liasions with the ladies. One thing I noticed was that those women who deny themselves the pleasure of food, denied themselves in other pleasures as well.

It evolved in to a hard fast rule that if she ordered "only a salad, I am on a diet" she was taken home right after dinner and removed from future consideration.

The women that were the most enjoyable in all aspects can be characterized by Annette Funachello. I actually got to meet her once as I used to go out with Candy Johnson. You might remember her as the short haired blonde dancer with the fringed outfits in all the beach movies.

As the song goes "Those were the days my friend"

Except for the serious problem of the nutball factor out there, I agree.
I lived in Anaheim for 7 months while working on a Honeywell/Ericsson
project in the late 80s, and I wouldn't take one of those women without
a 110% money back guarantee.

Richard:

You should be advised that modern semiconductor driven diesel injectors are noisier than Kettering ignition systems.
DIN and the rest of the European regulatory bunch have really clamped down on spark fired ignition noise, but apparently
Diesels have escaped their attention.

The fitted radio, thanks to my skinflint boss is a "bare minimum"
Mercedes branded unit, actually made by Becker, I believe. It is
therefore a good quality, if basic, piece of kit. The antenna is I
guess from the same "box" ie standard quality etc. FM reception, for
instance is OK. All the truck electrics, including the radio are 24V,
albeit from 2 X 12V batteries in series. The built in unit is JUST
tolerable on AM when there is a really good signal ie in the UK, if
the signal is at all weak (I am guessing here), other noise dominates
ie a rhythmic low frequency "fart" noise, (I guess this comes from the
tachograph, stupidly fitted next to the radio) A whine, related to
engine revs (alternator?? fuel pump??) horrible noises whenever I pass
under a bridge or anywhere near power pylons or railway lines.

The portable radio (with its own batteries 8 X D size = ï¿½24.00 or
approx $40.00 the set) has markedly better Rx even when just outside
the cab, on the step for instance, and strangely seems not to be as
badly affected by the bridges and pylons

4457. Using 450ohm ladder line

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-19 12:24:13 UTC
From: Giovanni <gsantin@mclink.it>
Message-ID: <1124454253.543768.193870@z14g2000cwz.googlegroups.com>
Source record: 71725

I have the possibility to run a 450hom ladder line from the rooftop
down to the shack in the basement of the house, through an unused
chimney made of a steel pipe of about 1 foot of diameter and about 20
feet long. If the multiband dipole antenna to be feeded is balanced,
the feed line should not radiate so it should not matter if it is
shielded.
A balanced antenna tuner in the shack should take care of any impedence
variation of the ladder line.

Advice on this implementation will be very much appreciated.

Many thanks,
Giovanni IW0BJR

Only too true. When mobile I can hear Mpls buses about 100 feet away over the S5 downtown noise on 20 meters. They make an interesting tone pattern that I surmise may have to do with resonances in the various lengths of the wiring harness involved. I've heard much the same from some, but not all, diesel trucks.

I wonder if the radio has a trimmer capacitor like many of the US AM BCB radios have had over the years. You would normally have to pull the radio from the dash and inspect it to see. If it does, it may help a bit to tweak it.

What is the model number of the unit? Maybe we can find an online user's manual.

The ladder-line needs to be centered in that 1 foot diameter
steel pipe. Otherwise, the fields are likely to become unbalanced
and losses occur. 6 inch spacing away from any conductive medium
is just about right.

I didn`t have a clue. My experience is out of date. Injectors were timed by a camshaft which generated little electrical noise.

Methods used to control radiation from Kettering ignition systems and their solid-state derivatives should work on fuel injection timing systems too.

The plan is to keep the electrical noise within a screened enclosure and not let it out. It is hard to believe there is no DIN specification for radiation from electrically timed fuel injectors. In the old days ther was a specification for about everything.

==========

There is no great need to exactly centralise the feedline inside the
pipe. The amount of radiation from the balanced feedline feeding a
balanced antenna, inside the pipe or not, will be negligble.

Loss induced in the metal pipe will also be negligible. The
resistivity of steel is very low.

With a 1 foot diameter pipe the decrease in line impedance Zo will
also be negligible.

As a precaution, if the chimney is not vertical, try to keep the same
wire of the line away from the chimney walls for appreciable lengths.
Very slowly, about every few feet, twist the line about itself.

After construction, if the line is moved about and there is no
difference in the tuner setting then there's nothing to worry about.

Reg, G4FGQ

Message-ID: <d4fd4$430600b9$48317931$15319@FUSE.NET>
Source record: 71634

Cecil, no argument. All I meant was the theory behind a G5RV is the same as an EDZ. Nothing more. The G5RV provides a better pattern than an EDZ at the expense of some gain, but basically the design criteria is the same. The original G5RV was never intended to be anything but a 20 meter antenna (at least as far as I've read). The fact that it works on other bands is just icing. I use a 'modified' G5RV, similar to what Cebik describes on one of his web pages (think it's the ZS6BKV design) and found it to be a better G5RV than the original and it's shorter. Think mine is around 94 feet long. I've also built a 20 meter EDZ (still have it rolled up in the garage) and found it to be a great antenna but the beamwidth was too narrow to live with. BTW, for what ever reason it worked really well on 15 also. My 94' antenna works well on 40,20,17,12 and part of 10. It will load on 75, but not sure how well it radiates. SWR on the other 5 bands is under 2.5:1 at resonance with 40 and 20 under 2:1.
Holy cow, I would never argue with you guys. I guess my main point is that all of these type of antennas are collinear type antennas and to get the best performance from them, they need to be in a flat top configuration. However, you work with what you have and if that dictates a Vee or L configuration, then you do it.

Simply tap off at the junction of the two batteries. The truck series two 12 volt batteries to give you 24. Find the the junction where the plus of one is tied to the minus of the next. Tap off a wire at this point. I would fuse it at the connection point. This will provide the necessary voltage for the radio.

CAUTION! I have made the assumption that your truck has the chassis tied to the negative side of the first battery. In the event you have a positive ground truck let me know and I will tell you how to get around that problem.

Stephen Parry wrote:
"Yes I think I do have alternator noise could you explain what I might do?"

Often the first sign of diode failure is a whine in the loudspeaker of your radio which varies in pitch with engine speed.

Alternators have no commutator but use silicon diodes to make d-c from the a-c they generate. It`s usually 3-phase, using (6) diodes in (2) groups of 3 each in a full-wave rectifier. These are located inside the alternator. If any of the diodes fails, at least one of the 3 pahases quits contributing to the alternator output. Maximum output is reduced. Replace the diodes. The whine goes away and full output is restored to the alternator when required.

Stephan also wrote:
"I think we might have been divided by our common language!"

What Americans call a hood, I believe, is what the English call a bonnet. The effectiveness of a screened enclosure depends on good connections between its pieces.

In a modern diesel truck there may be noise generating electrical fuel-injection control, rotating belts which generate static discharge noise, electrical relays and contactors, and other sources of radio frequency noise.

Noise containment is one goal of the bonnet. The hinge which holds the bonnet and the latch which locks it are often inadequate in r-f continuity. Their electrical contact is not good enough.

Wheels rotate on stationary spindles and axles. Rotation can produce charge which repeatedly arcs across wheel bearings or other points. Spiral springs are made with a large diameter on one end to rest on a stationary part of the wheel assembly. The spring tapers down to a small diameter or point on its other end. This point makes contact with a hammer-on cap over the nut which holds the wheel on its spindle. The cap rotates with the wheel. So we have a conducting connection between the wheel and the non-rotating parts of the vehicle. Only extreme noise cases require these springs.

Stephen also questioned what I meant by perfect antenna cables. I once repaired rafios and my experience is that most noisy automobile receivers got that way from defective antennas and antenna cables.

The base of the antenna needs a good connection to the vehicle body, which is the other half of the antenna. The vehicle body is the

connection for the cable shield. The shield needs to be continuous to carry the signal rather than having the body carrying the signal where it may be exposed to noise currents.

I wrote:
"Keep the antenna away from and shielded from sources of interference."

When one installs an antenna, it should be placed in a quiet receiving location if possible. It should not be installed on the same side of a screen as wires carrying interference. The antenna should be installed on the outside of the truck cab where it has large exposure to the signal.

When I said bonding, I did mean a clean earth return but I was not thinking of battery current. I was thinking of r-f currents, signal and noise.

Radio frequencies don`t penetrate deeply into metal but travel on the surface. Large surface area is needed for low r-f impedance. Battery current uses the entire cross section of the metal.

Wires slung under running boards and the chassis are not much used now. Other noisy conductors may be nearby Broadcast ground waves are vertically polarized. It makes sense to use a vertical whip for reception, though almost any wire works.

Stephen`s portable likely has a loop antenna inside which makes it somewhat bidirectional in azimuth. A vehicle mey be found in any position. This makes an antenna which is nondirectional in azimuth desirable.

Best regards, Richard Harrison, KB5WZI

4470. Off topic. Statistics.

Having temporarily run short of suitable radio topics to write
programs about, I came across an older program of mine which people of
your intellect might be inerested in. Play with. Or use even.

Program HYPERGEO(metric) solves an extremely wide range of important
statistical problems. Basically, it is involved with "The
Significance of the Difference Between Two Proportions". Input data
is in the form of a so-called 2-by-2 Contingency Table. Just 4
numbers.

EXAMPLE 1.
Manufacturing Quality control.
We take a relatively small random sample of N1 widgets from a large
batch of widgets and find that a number D1 of them are defective.

We then take a relatively small random sample N2 from another
manufacturer's large batch and find that that a number D2 of them are
defective.

The question arises, which manufacturer's product has the highest
quality. Bear in mind it is expensive and time-consuming to 100
percent inspect both batches. It may be agreed in advance to inspect
only a few percent of the batch sizes or just a fixed number
regardless of batch size.

So we are obliged to ask the question - from the two samples, is one
manufacturer's quality REALLY better than the other? By how mutch is
it due to the random selection of a relatively small number of
individual widgets from a batch? Probabities are clearly involved.

EXAMPLE 2.
Medicine and Health of Populations.
There has been an epidemic. A fraction of the population were
innoculated against it. Out of a sample of people who have been
innoculated a number N1 did not suffer from the disease but a number
N2 did suffer and die.

Out of a sample of people who were NOT innoculated a number N3 were
not affected by the disease but a number N4 suffered and died.

The question arises, how effective was the innoculation? It may
possibly have had adverse affects. The answer is a matter of
probability statistics. International Pharmaceuticals please note.

There must be other applications in the relatively narrow field of
radio communication, perhaps involving the randomness of noise,
crosstalk and interference. 2-by-2 Contingency Tables, just waiting

for analysis, arise all over the place.

Anyone further interested can look up the works of Sir Ronald Arthur Fisher. For example, a collection of his works can be found in - "Statistical Methods, Experimental Design and Scientific Inference". An international master, Fisher was involved with the fields of statistics, agriculture, genetics, mathematics, engineering, biology, medicine, etc. Before the age of electronic computers he devised new statistical tables such as the F-Distribution for ANOVA. He died in 1962.

Fisher's writings are works of logical plain simple English. The maths are few and don't get in the way. Like Heaviside, a revolutionary. His opinions of earlier workers are scathing.

After many years of haggling between prominent statisticians about the correct interpretation of the apparently simple 2-by-2 Contingency Table, it was Fisher's logic which ended the arguments.

Despite its simplicity, the numbers involved in the probability calculations are so large it is necessary use their logarithms to prevent numerical overload of ordinary computers.

Within the next few hours I'll make program HYPERGEO available from the following website. It would be a pity should it be lost.

There is a 3-phase transmitter feeding a 3-phase antenna via a 3-wire
transmission line.

The antenna consists of three 1/4-wave horizontal radiators spaced at
120 degee intervals.

Is the radiation pattern in the horizontal plane perfectly
omni-directional?

Hi Reg, Is the 3-phase transmitter balanced with the output current equal magnitude, and the phase angle exactly 120 degrees? Is the 3-phase antenna fed via a 3-wire transmission line, or three equal length transmission lines? Us Amateurs don't have a lot of experience with 3-wire coax. Are the horizontal radiators 1/4-wave, or 1/2 wave? If they are 1/4 wave, or 1/2 wave and spaced 120 degrees in the horizontal plane, doesn't that form an equilateral triangle? So, you are feeding a triangular antenna whose sides are 1/4-wave in the centre of each side with balanced 3-phase rf energy?
Even if you clarify this is I still won't know the answer to your question until I model the array.

=====================================

The three antenna wires are like the spokes of a wheel, spaced at 120
degrees, and each 1/4-wave in length. All in the horizontal plane.

The transmission line is balanced about ground and each of the line
wires is connected to one of the three antenna elements at the center
of the wheel. There's no need to pull the line wires apart at the end
of the line.

What is the radiation pattern in the horizontal plane?

Also what is the equivalent load impedance between each of the line
wires.

Reg.

4480. 80 meter loaded vertical versus 80 meter loaded dipole ?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-20 00:21:58 UTC
From: dansawyeror <dansawyeror@comcast.net>
Message-ID: <PeydnRlla6c06pveRVn-tw@comcast.com>
Source record: 71648

All,

I have been using an 80 meter loaded vertical for a couple of years with moderate success. The ground system is a dozen 'untuned' radials 40 or so feet laying on the ground. The feed line is about 100 feet of RG-8 coax. The SWR in the shack is about 1.1 to 1.

I have done some research on the antenna and based on it parameters it should have a radiation resistance of about 4 Ohms. This says that the coil and ground are absorbing on the order of 45 Ohms. This is 10db performance loss.

I have limited space and the most common solutions are not available to me. From a practical perspective it would seem to me that building a 40 foot center feed loaded dipole and putting it in the attic or on the roof would probably perform somewhat better.

Is this a reasonable assumption?

Would burying the radials and connecting them to several 4 square foot buried screens substantially help the ground system?

Thanks,
Dan kb0qil

Actually, I think it is delta connected. A Y connection would Imply half
wave dipoles with their feedpoints connected between each of the three wires
and the neutral point. I am holding my breath for the answer.

Cecil:

If I understand a lot of data which has been gathered, it tends to imply
"things" can go faster than the speed of light. The princeton egg project
is working on the edge of such things:

http://noosphere.princeton.edu/

... interesting stuff...

I do understand this correctly, and each antenna is fed a signal 120
degrees out of electrical phase with the other 2. And, the physical
placement of the also happens so as to place any specific one of the three
antennas 120 degrees ahead/behind the other two in a physical circle?

BKR:

Reg has " There is a 3-phase transmitter feeding a 3-phase antenna..."

Does this mean the transmitter is powered off 3-phase 60 cycle (if so, really doesn't affect the antenna) or is the transmitter final somehow constructed with a tank supplying 3-phase rf???

Then the "3-phase antenna", is each monopole, dipole fed though different lengths of feedline, with one 0 degree length, one 120 degree length, and one 240 degree--electrical lengths?

Those brits can be tricky yanno! <grin>

I think he was providing a simplified model by eliminating phasing
lines. As I understood it he meant that there 3 outputs from the TX
with 3 equal length feedlines or a special feedline, and that all are in
a rotating 120 degree progression.

I have limited space and the most common solutions are not available to me. From
a practical perspective it would seem to me that building a 40 foot center feed
loaded dipole and putting it in the attic or on the roof would probably perform
somewhat better. ....

Probably so for short/med haul. Will be a toss for long haul.
Even a semi lossy vertical can outdo a low dipole to dx if the
path is long enough. But for talking 200 miles away, the dipole
will blow the vertical away.
12 radials is not many for a ground mount. If you were to add
more radials or screen, I'd do it at the base of the antenna.
IE: add 50 10 ft radials for 500 ft of wire... Should be better
than a few full size radials. Some say screen can cause problems
after a while do to corrosion. I'd probably just stick with wire
radials myself... How far you want to talk on that band should
determine what antenna is best. For most general use within
1000 miles, I'd rather be on a dipole than a vertical.
But dx, I'd go vertical, and improve it. Loaded does not have
to mean crippled. But loading/short verticals do make the ground
system more critical. My mobile is better than my home dipole
late at night on 40m if I'm talking over 1000 miles away...
And if it ain't loaded, I dunno what is...What power it radiates
is at the perfect fairly low angle for that path/time of night.
BTW, I'd install the dipole outside if at all possible. Less noise
from the house, and will generally work better. Won't hurt it to
be close to the roof, unless metal is underneath to detune.
I've layed dipoles directly on composition shingles with no
problems at all. Or at least when dry anyway... But elevated a
bit would be better.

With a delta connection the line wires would have to opened out at
their ends and would radiate just as much as the triangular antenna
itself.

With either delta or Y connection there is no 4th neutral wire. As the
whole system is balanced there would be zero current in the neutral
anyway.

You are describing the Y connection. With delta connection the load is
between adjacent wires of the feedline. Look at any two wires of what you
describe, and there is a 1/2 wave dipole, center fed, formed by two of the
1/4 wave radiators. But, instead of the two halves of the dipole being fed
180 degrees out of phase, they are 120 degrees. Each 1/4 wave radiator is
part of two different dipoles. Each dipole is bent 60 degrees at the feed
point.

As for the feeedline, I presume what you have is like a twisted pair, but
there are 3 wires, not 2 You could not use a flat transmission line because
it would not be symmetrical.

Hello Dan,

Some thoughts:

The 10 dB loss is, of course, referenced to a "perfect ground." Even with a full length (quarter-wave) vertical and your ground system, performance would improve by about 3 dB. Not a blockbuster.

Improving the radial system, as noted by others, is a more realistic course. You ought to be able to get the ground resistance closer to 20 ohms with more radials close in. Then you will be only 6 dB worse than if your ground were perfect.

Putting up an indoor dipole is cheap and quick. Put it up and compare it with the vertical. But don't hold your breath. You will probably find that with some paths, the dipole is better. you may want to keep both.

I assume you've ruled out a capacity hat, center loading, and a coil with lower losses, as suggested by others. But with these changes and an improved ground system, you might get a full (6 dB) S-unit improvement.

Good luck.

73,

Chuck

MK,

Thank you for your reply. I will defiantly try adding radials. It may be easier to lay down screen mesh then 50 10 foot radials.

Have you measured the impedance of your mobile vertical? Is it a simple loaded vertical or is there a matching network?

Thanks,
Dan kb0qil

No. Effectively you are feeding two legs with a -120 degree phase
and that will make it directional.

For Omnidirectional operation ALL legs will have to be fed in phase.
If the three sources are laggin in phase then the feed system will
have to correct the phase till all are in phase.

Many years ago, there was a CB (USA 27mhz 11m) that used three
vertical dipoles with phasing to get directionality or omnidirectional
gain.

nospam:

That cb antenna (with the 3 dipoles arranged so as to go omni/directional) was called a "scanner", made by antenna specialists I believe (reed switches in a relay box control the elements.)

I cut one down, along with the phasing harness to the center of the 10 meter band, works great! And you are correct, the three 120 degree spaced vertical dipoles are fed in phase for omni-pattern.

John

When I first got my technician ticket, my assigned call sign was KI4FAT. After about 6 months, I retired from the Army and applied for and received a vanity call sign of WO2RET. I'm proud of my status both as a military retiree and an amatuer radio operator. When someone asks me what the call sign stands for, I just tell them it means exactly what it says. I also have an amatuer radio operator vanity plate on my car.

As for G4FGQ, the highest compliment I ever had paid to me was after I had been DXing on the 2meter band using a home made Jbeam, I heard an old timer telling the indivual I had been talking to that he didn't catch the call sign but 'that ham with the home made antenna had really done his homework and put it together right because the signal was outstanding.' To have an old-timer call a relative newcomer a "HAM" is probably one of the greatest compliments a person can receive.

Just my 2 cents worth.

Bill, WO2RET

Frank,

The coil measures about 60 uH. The antenna is elevated about 3 feet on a short tripod. The radials angle down the tripod legs and then out.

The coil is about 4 inchs in diameter, number 12, wound on a fiberglass form. It is centerloaded. I am looking at it accross the yard, it is about 6 inches long. It is would with about a point .5 pitch. Calculations for a 1:1 pitch predict a Q of about 450.

Thanks,
Dan

The local gardener who takes great pride and ownership in the lawn. The garage can go mostly to seed, however the lawn must be pristine. Each antenna change meets with great resistance. Although defiantly was definitely a spell checker choice, it is also the correct one for getting radials.

Many years ago I help a ham friend (now SK) set up a foursquare. that
four vertical monopoles with goundplane with phasing feed for gain and
directionality. It was a very good antenna for 20M.

Early in my commercial career I worked part time for an AM BCB station
and would help with antenna tuning for directional pattern. Imagine
three big (300ft) towers in a field with about that much space between
them in a line. The feed and phasing coils were BIG, the usual
pattern was cartioid with the weak null facing the atlantic ocean to
the southeast. Just a bigger version of many phased arrays I'd see
in my commercial career.

Hi
I just picked up a (stoner) Dymek DA9 active antenna. The tuning cap has somehow been bypassed and it does nothing to affect the station. I was told that this was bypassed intentionally so as to be a broadband antenna. I'd like to resore ti to original and use the tuning cap as a preselector.

Does anyone have a print / schematic on this unit ?

Thanks!

I am glad they call me an Amateur, because that is what I am. The word Amateur is in the name of this Newsgroup. It is obvious Professional Radio Engineers would understand what Reg was talking about, but this is an Amateur Newsgroup. Why don't you go to the Professional Antenna Designer Newsgroup (if there is one) and ask the question that Reg did? I don't think they would all understand perfectly, but I may be wrong, because I am an amateur. By the way, are you an Amateur Radio Operator?

I ran EZNEC on what I think is an equivalent arrangement, and got a gain max/min ratio of about 4db. Got an impedance of 29 Ohms. With multiple sources, I have trouble visualizing what that means. That may actually be 87 Ohms line to line.

For those folks who aren't all that familiar with transmission lines. .

Velocity factor refers to phase velocity, and the VF of all hollow waveguides is > 1.0.

Of course, the group velocity is always < 1.0, and that's the rate at which information can be conveyed. I don't believe for a minute that this rule has been broken.

Hi Tam,

What do you mean by that? You have a source pushing current into an element against a counterpoise, an active one albeit, but all counterpoises support current too (hence the symmetry of resistance). Just another condition of the ENTIRE structure radiating energy (where some would have energy cancelled rather than the power product into a remote load).

Yes, the three leaf trifoil is not very pronounced, and only below an elevation or 45 degrees or so. However, Reg introduced this with the strong suggestion of perfection. Perhaps his usual indirection. ;-)

A 4-phase antenna shows a similar lobing to a smaller degree, and a 5-phase antenna is for all practical purposes circular.

I had to solve a problem like this a couple of years ago with a design for the Army to test their Helicopter pilots for mental alertness. This involved building a uniform field of even illumination over a visual angle of 180 degrees horizontal and 90 degrees vertical (roughly the entire field of view). I was tasked to present no more variation than a couple of percent ripple. It took about 100 light sources 1 cM from the eyes.

John, picture if you will, an observer on earth watches a spacecraft pass between the moon and the sun at 99.9%C. The occupant of the space craft knows that the distance is about 93 million miles and clicks his stopwatch as he passes the moon, and again as he passes the sun. Given the time and distance, he computes his speed (measured with his slowed down time piece) and concludes he has exceeded C. Ergo there must be analogs of C. What say you?

Entangled particles may not violate the letter of the speed
of light limit but they certainly violate the spirit of the
limit. When man figures out how to change the entangled particle
generation pattern from random to predictable, we will have
faster than light communications. It's just a matter of time. :-)

Fred:

Quite obviously, there is no such thing as time.

However, since he is attempting to discern if there is a change in his speed (rapidity at which he is transversing the ether), against a speed which we now claim as a "law"--i.e. speed-of-light, he must attempt something, and measure it against some other spinning object (namely earth, when he uses his watch.)

He would actually need to throw away the watch and race a laser beam on a parallel course to himself, which is originating in a third place behind him to get any meaningful measurement at all, as all he is interested in is how fast he is traveling in relationship to light transversing the same media as himself.

But he is doomed to failure, as surely you must see. Time = movement = distance, since there is no such thing as time, it is actually distance (or space itself in between points he travels) which he is really causing to change, and to my knowledge, we have not yet constructed the device which can measure such, but a shortening of distance is obviously happening between him and his destination, those lines of ether which connect him to his destination are being warped in someway not understood, probably being bent back upon themselves like a horseshoe, and now he is not actually traveling the distance around the horseshoe, but rather, stepping across the two ends.

Ether, the real "matter" of the universe, passes though our altered state (caused by the big bang ripping our "matter" from the real matter the universe is composed of and altering its properties into "our matter") like a gas though a screen composed of very large holes. At the speed of light this resistance of our bodies to the flow of ether though them fails to remain insignificant, what happens next, when our matter finally becomes a real resistance to ether and then goes further to "push" the ether in a flow not of its' own design, and in a way we have never seen done since the big bang, is unknown...

... but, I do think upon these things ... and others claim there is nothing to even be thought upon ...

... but then you already knew there was no way to answer your original question, at least not correctly ...

I thought the multiple meanings of, "It's just a matter of time.",
was humorous.

Consider that the complete quantum state of a particle could be
teleported to Mars and back to Earth without suffering the speed
of light delay. This has already been demonstrated in the physics
lab. Unfortunately, all quantum states must necessarily remain
unknown until the complete quantum state is teleported back to Earth.

Hi Richard,

My main problem was interpreting what EZNEC meant when it told me the impedance was 29 Ohms at resonance. Missed the fact that it displays the Z for each generator independently. 29 is the impedance to neutral. So, that makes it 87 Ohms line to line. I did this in free space. There is no NET current in the neutral.

Tam

Hi Tam,

I took the more practical (amusing given the absurd complication of a
3-phase RF source) route of putting the antenna ï¿½ above earth.

Cecil:

"It boggles the mind.", is often an over-statement. Here it is not. It is no doubt many would question the sanity of men who even are so brazen that they would ponder such things--in other words, I think we are going to have to take a little flack over all this...

It is why I pointed out princetons' egg project. You see how careful they are, the detail they even pay to picking the words they choose to even advance discussion of the matter, least they be branded "kooks."

It will be exciting when we are even able to grasp the smallest detail of the functioning of all this...

Well Me, as for me, Amateur since 1963, professional radio engineer,
never. I did install some cb antennas during the early 1970's and got
paid, so I may be a professional antenna installer? Hope by these acts
I didn't give up my Amateur status. Was in college at the time and did
not have much $$. Why don't you give your call?

Maybe I missed something, but how high is the TOP of the antenna. I.E. How
long is the whip? Is the loading coil at the base, or partway up the
antenna?

Tam,

The description was for the coil.

The total antenna is about 15 feet base to tip. The coil is about 1/3 of the way up. The base is about 3 feet off the ground so the tip would be about 18 feet up.

Dan

Dan,

Over perfect ground, I get an impedance of about 2.4 Ohms, with resonance
very close to 3.8 MHz. What is the tallest tree in your yard?

That would relate very close to what the models predict. Where or how do you have such good ground?

I'm not sure you can count on that. You'd still lose some in a matching/loading network, there'd be a lot of ground loss because of the low height, and absorption of some of the power from conductors in the house might occur. It wouldn't hurt to try, but leave your vertical up.

> Would burying the radials and connecting them to several 4 square foot
> buried screens substantially help the ground system?

Just about anything you can do to increase the conductivity of the ground system, particularly close to the antenna, will help. Using screen is one thing. Burying the radials won't help. Adding more radials and making them longer will help. Unfortunately, making a few radials longer doesn't do much, and adding a bunch of short radials doesn't do much either -- you really have to do both to have a big effect. If possible, connect to any other nearby buried conductors such as metallic water pipes.

The other thing you can do to improve the efficiency is to increase the radiation resistance of the antenna. You can do this of course by increasing the height of the antenna. Moving the loading coil upward will help, too, although you'll need more inductance. (The coil still won't be a major part of the overall loss, though.) A top hat is better yet. You can also increase the radiation resistance by making your antenna fatter. Use multiple wires in parallel, spaced about as far as

you can, either along side each other, or fanned out, converging at the bottom.

Finally, if you've got room, you can improve your overall efficiency by about 3 dB by putting in another identical antenna/ground system somewhere nearby and connecting the two in parallel.

As I am getting closer to retirement I have been thinking about buying a used spectrum analyzer since I will not have access to one at work. Unfortunately I am not familiar with all the models from say 5 to 15 years ago. Is there a good reference describing the different HP/Agilent, Tektronix, etc. models and which are good and which to avoid. A quick look on Ebay shows HP 4195A, 8561E, 8562A, 8562B, 8563E,8565A, 8568B,8569B, 8591E, 8593E, and 8594E. Similarly for Tektronix 492P, 494P, 495P, 495A, and 2755P. Is there some kind of a used buyers guide available. I understand spectrum analyzers at a moderate level and realize the differences between frequency range, external mixers, dynamic range, bandwidth etc. but finding the specs in a manner that makes them comparable is hard. Thanks for any advice.

Never seen a buyers guide for spectrum analyzers. They all seem to have about the same dynamic range. The factors that really drive price are upper frequency range, tracking YIG filters, and selectivity. Do you really need 26.5 GHz, and a 10 Hz IF filter, if not you could probably save a lot with a 2.7 GHz upper limit. Then there is the HP analyzers that use the 141T storage display, that can be purchased for a very low price. I have seen many at Dayton. I would never buy a storage display without seeing it in operation though. Anritsu also has a nice line of analyzers.

I would use www.tucker.com or www.tesequity.com as a guide to the prices you could expect to pay. There are many other used test equipment dealers.

You don't. That is just the best case. If you can add another 20 feet of
wire to the top, and redo the inductor, the Z comes up to 16 Ohms. That's
why I asked about the trees.

Thanks for the info Dan. From your comments the radials appear to be parallel with the tripod legs to ground level, and then continue at ground level for the rest of their length. What is the angle of the tripod legs? I agree with comments about adding a horizontal wire to the top of the vertical; it will probably be easier than a capacity hat. I am overloaded with work at the moment, but would like to attempt a model in a week or so when I have less work.

Larry, can't really offer any guidelines to your search, but wanted to mention that you should add IFR model A7550 to your list. I have used these for many years prior to retirement and they are a great instrument. Every so often I see one going quite cheap on Ebay.

My "rule of thumb" has always been.... HP for spectrum analyzers,
and Tektronix for Oscopes..... Fluke for Dvm's and Lambda for Power
Supplies.

Take a look also at a tee type arrangement. That is, a horizontal wire with the tip of the vertical connected at or near its center. It might have some advantages over connecting the wire's end to the vertical. But of course it might be more involved to construct.

Dan, KB0QIL wrote:
"From a practical perspective it would seem to me that building a 40 foot crnter loaded dipole and putting it in the sttic or on the roof would probably perform somewhat better."

The roof or attic may be noisy receiving locations.

The ionospheric spot which effectively reflects a high frequency signal to a point beyond the horizon is variable so that the received signal direction varies from the true bearing of the transmitter, The received signal elevation angle also varies from that predicted by the assumed layer height for any given path length, and may change from instant to instant.

The differences between predicted and actual azimuth and elevation angles may at any momement be several degrees. These differences make high frequency direction finding complicated, but results may be good enough for some pracical purposes. Optimum vertical and horizontal angles are sought in directional antenna design but enough beamwidth is needed to accommodate
the angular variations which occur.

Over sea water, ground wave propagation is good and loss is low as compared with propagation over earth. Frequencies up to about 5 MHz are used for communications beyond the line of sight between ships and between ships and shore. These frequencies are also used for tropical broadcasting among islands.

For ionospheric reflection to near spots beyond the line of sight, near vertical incidence reflections are used. The frequency must be below the maximum usable frequency for vertical incidence at the transmitting site.

For ground wave propagation a vertical transmitting antenna is used.

Horizontally polarized antennas are often used for sky wave signals because reflection from the ionosphere makes equal strength components, horizontally polarized and vertically polarized, from the incident wave, regardless of its initial polarization.

Most disturbing noise is that generated within ground wave range of the receiving antenna. It is vertically polarized.There is no ground wave propagation of horizontally polarized waves. Thus, a horizontally polarized receiving antenna ignores much of the available noise. However, it receives as much signal from the sky wave as a vertically polarized antenna would.

If a single antenna is to be used for both transmitting and receiving a shy wave, a forizontally polarized antenna may be the better choice due to its noise rejection. See "Radio Antenna Engineering" by Edmund A. Laport for details.

Best regards, Richard Harrison, KB5WZI

Richard,

I am impressed by your logical descriptions and explanations of skywave and groundwave propagation. You are more than convincing. No doubt reinforced from practical experience. It all makes sense. Something much needed on these newsgroups.

I notice you do not treat the works of so-called 'experts' as bibles but as a means of further study.

Reg, G4FGQ

4554. Info needed TA-33SR Choke coil

Newsgroup: rec.radio.amateur.antenna

I am putting up my old TA-33SR by Mosley. I need to know how many windings are needed on the choke. I seem to remember 6" diameter, but not the amount of windings.

According to the manual there is no choke indicated at all.

Anyone know anything about this?

Dan/W4NTI

Dan, I am unable to help you.

Because, in common with most other people, I havn't the foggiest idea
what a TA-33SR is.

Questioners would do better by not depending on other people's
imagination. It takes only a few seconds to provide a little more
essential information. If you can't find the time then it can't matter
very much anyway.

Reg.

Reg, even to me (a relative newbie) "Mosley TA-33SR" provides all of the information needed to identify what Dan is talking about. A very brief Google identifies as a triband trap beam. I have little doubt that anyone who has ever owned one (and is thus likely to have the direct information that Dan is looking for) would recognize it from his description with no further description being required.

Dan - since Mosely's manual doesn't mention such a choke, and the instruction sheet indicates a direct attachment of the coax to the driven-element feedpoint terminals, I doubt that the details of the choke are terribly critical. You could probably use any of the plans on the net for an air-wound coaxial choke-balun. One plan I see uses 18-21 feet of coax, close-wound solenoid-style on a 5" PVC form (stated to be good for 160-10 meters).

Another site (http://www.bcdxc.org/balun_information.htm#Ed,%20WA2SRQ) has a table of air-core balun impedances, as a function of both frequency and construction (turn count and diameter). This chart suggests to me that 4 turns, 6 5/8" solenoid-wound might be a good option for you, as its impedance peaks at around the 15-meter band and is 500 ohms or better between 10 and 20 meters.

Some folks seem to prefer solenoid-wound air baluns, others prefer scramble-wound. There seems to be a fair bit of disagreement as to

which style works better, and why.

The other choices are to use a different sort of balun (e.g. a W2DU ferrite-bead choke), or none at all.

Hi Dan, The choke on a 3 band Yagi is to decrease feedline
radiation, a choke balun. If you don't use a choke balun, you could
have some pattern distortion, it would deviate from the classical 3
element Yagi pattern.
I think the rule of thumb is have enough chocking impedance on the
lowest band (20M) so that it is 10X the antenna impedance (50 ohm).
You wind your coax into a coil that will accomplish this.
The TA-33's that I have seen did not have the choke balun. In casual
Amateur operation of the TA-33 I doubt you would miss the choke, or
know if it was there or not.

One possible method comes to mind... use an RF current probe to see how much RF is actually flowing on the outside of your feedline. I've seen plans for such probes, made from a clamp-on ferrite choke core and winding (making a simple RF transformer) plus a diode, cap, and meter.

In order to distinguish conducted RF (which the balun would be expected to be able to stop) from induced RF from the antenna itself (which would probably go right around the balun) you might want to try disconnecting the antenna itself from the output of the balun, and substituting an equivalent resistance/reactance at the frequency of interest. Push a few watts into the "dummy load", run the current probe down the feedline from the balun to your rig, and see what the peak current is. Repeat at multiple frequencies, and (if practical) with different feedline lengths. Using a half-wavelength-long coaxial feedline would probably maximize the sensitivity of the test, as it would present a low RF impedance on the outside of the coax at the "bottom" of the current balun.

Repeat with other current baluns and compare.

To be complete, I suppose that you'd also want to measure the temperature of each balun before and after a high-power test, to try to get some feeling for the amount of loss in the balun itself.

Fred

I dont have the skills nor knowledge to tell you how to test the choke
balun. I do have some experience with testing of my home made choke
baluns.
I made connection to the shield of the coax that is surrounded by the
"choke balun", and measured the impedance across it. My reasoning was that
the major objective of the balun was to present a high impedance to current
along the outside of the coax.
It occurres to me that my reasoning might be invalid, since it seems too
obvious, and you already know the "impedance" test isnt adequet.

Fred:

With a toroid core, using the manufacturers data on uh/mh per number of turns, al factor and such, should allow you to compute the inductance and come to a value of the impedance that inductance poses at the operating freq(s) in question...

Major problem I see is a resonance(s) occurring with feedline length and the inductance chosen, but even that could be designed out with a pencil and paper... the physical testing you are inquiring about has my interest also...

You can measure the impedance by shorting the input conductors together and the output conductors together. Then connect the input conductors to one terminal of an impedance measuring device such as an antenna analyzer or impedance bridge, and the output conductors to the other terminal. An impedance of around 500 - 1000 ohms is generally adequate.

If you want to measure its effectiveness in place, you can construct a current probe like the one shown in Fig. 12 of http://www.eznec.com/Amateur/Articles/Baluns.pdf. It'll give you a quantitative measure of the feedline current. You can use a snap-on split core for convenience. The value at the choke should be very low, but it might increase considerably about a quarter wavelength down the line due to induced common mode current. The solution to that is to insert another choke balun at that point.

I have a toroidal pick-up coil slipped over my coax in the
shack to monitor the magnitude of common-mode currents.
That tells me how chokes, etc., are performing.

==========

Dave, having learned from you, a newbie, not from the enquirer, what a
TA-33SR is, and having inspected the website you specify, I am a
little wiser from reading the baffle-gab.

I agree with your recomendations. Just get a hank of coax, suspend it
in the feedline and away you go.

But it may be more mechanically convenient and electrically better to
wind a few turns of coax or Radio Shack twin speaker wire around a
ferrite toroidal core.

Or possibly do without a balun altogether. Try it and see what
happens. It's so easy to do.

Reg.

Hi Fred, If you have an MFJ antenna analyzer it is easy. You have
to measure the choking Impedance at the frequency of interest. Rule of
thumb is 10X the transmission line or Antenna Impedance, depending on
where the the balun is located. 50 ohm impedance, 500 ohm choke
impedance.
The 259 manual has a section on testing baluns. You can download the
manual from MFJ.

That your TA-33 manual calls for a 5-turn 6" diameter balun fabbed from coax is welcome news, Bill, Mr. Mosely must have gotten religion lately. I had a 33 when they were first made available, but no balun was included. So I had a talk with Mr. Mosely (I've forgotten his first name) and asked him why no balun. He became irate when I admonished him for excluding the balun. He said his antennas were designed to not need a balun, and he admonished me for claiming they needed a balun to avoid pattern distortion due to unwanted radiation from the feedline. He kept that same erroneous viewpoint for as long as I know, until your manual now calls for a balun. Will wonders never cease!

Roy,

Thanks. This might be feasible. The site would support 50 foot wire from the tip. At 500 watts what would the current in the horizontal leg be? In other words what is the minimum effective gage?

What is the purpose of this leg? Is it capacitive or does it begin to look like something else. What are it directional characteristics? Dipoles nodes are perpendicular while long wire nodes are parallel.

Fred, Roy's method is fine, but here's the second way I perform the
test with baluns constructed with ferrite beads surrounding a
transmission line. However, it does require two baluns.

To begin we connect the two baluns back-to-back, i.e. connect the
output of the first to the output of the second, and loading the
normally unbalanced input terminals of the second balun (now the
output) with a 50-ohm resistor.

Next, feed a signal into the input of the first balun and measure the
voltage between the outer surface of the line feeding the input of the
first balun and the outer surface of the unbalanced input terminals at
the output of the second balun. In the ideal balun the voltage between
these two points would be zero.

Next, disconnect the connections between the two baluns, and reconnect
them, reversing the connections. Now repeat the voltage measurement
between the same points as in the previous measurements.

In the ideal balun the voltage now measured will also be zero.

However, with a real balun, the voltage between the two points specified will usually be zero when the connection between the two baluns is such that the outer conductors and inner conductors of both baluns are directly connected, respectively.

But the real test of the baluns comes when the outer conductor of the first balun is connected to the inner conductor of the second balun, and the outer conductor of the first balun is connected to the inner conductor the second balun. The lower the voltage obtained in this condition, the better the balun. With a perfect balun the voltage will again be zero, but if the effect of the balun is zero the voltgage measured across the specified point will equal the input voltage.

The ratio of the voltage at the input of the balun to the voltage appearing at the points specified above is twice the ratio of the forward voltage to the common mode voltage that would appear on the outside surface of the feed line when that balun is used in practice.

Reg, G4FGQ wrote:
"There is a 3-phase transmitter feeding a 3-phase antenna via a 3-wire transmission line.

The antenna consists of three 1/4-wave horizontal radiators spaced at 120 degree intervals.

Is the radiation pattern in the horizontal plane perfectly omnidirectional?"

The question is easy, I think. The horizontal 1/4-wave elements have nulls off their tips, so they can`t produce a perfect omnidirectional pattern.

Not knowing when to quit, I`ll also speculate that at distant points from the antenna, the total phase from two elements will produce a total phase difference of 180-degrees which consists of a total of radiated field degree difference and path distance degree difference. Maybe more nulls. I wrote "two elements", because I`m thinking of a dipole in a V configuration with the 3rd element perpendicular to the dipole as being more or less along for the ride. Perhaps that`s an oversimplification.

Someone likely has a program which will model Reg`s 3-phase antenna. I don`t, and I have no experience with 3-phase antennas. I`ve done 3-phase circuit problems and recognize the balanced load, even if the antennas are unbalanced.

The system is symmetrical, so each of the loads (antenna elements) takes the same power. The total load power is 3 times the power of a single element.

The loads are resonant, so (cos theta) is unity. The elements look like resistors. Element power is element volts times element amps.

The load is equivalent to a Y-connection.. So, the line to line voltage is the square root of 3 (1.732) times the volts between the line and neutral.

Reg also wanted to know the impedance of the antenna, I believe, but its numerical value depends on construction, height of the elements, their size, and coupling, if any, to their surroundings. 35 ohms might have been a good guess.

Voltage to current ratio of the elements gives their resistance.

The volts or amps of the balanced 3-phases can be represented by three equal arrows separated by 120-degrees. Their instantaneous values always total zero.

The idea of a polyphase antenna is interesting but I don`t see what justifies its increased complexity, unless it happens to place nulls exactly where needed for required protection of broadcasters already on the air or permitted when a new broadcaster is seeking accommodation. In that case, the elements would most likely be vertical to launch a decent ground wave.

Best regards, Richard Harrison, KB5WZI

To determine the horizontal wire current, download the free EZNEC demo from http://eznec.com. That's exactly the kind of thing it's good for.

If you put a single horizontal wire out to make an L shape, the wire radiates a considerable amount. Being as low as it is, a lot of the power will be dissipated in the ground, and only a small fraction will be radiated at a low elevation angle. But if you connect to the center of a horizontal wire to make a T shape, the fields from the two halves of the horizontal wire will nearly cancel, so it'll radiate very little. Its main effect, like a capacitive top hat, will be to even out the current in your vertical wire, which will raise the radiation resistance and therefore the efficiency.

EZNEC or a similar program will quickly show you the differences in field strength in various directions for the antenna as it is, and with either of the top loading configurations.

I recall helping put up a beam for the Denver Radio Club station in about 1972 or 3, and one of the instructions was to wind the coax into a choke at the feedpoint. At the time I didn't understand quite why or what it did, but it was there in the instructions. Don't recall what kind of beam it was, but considering the popularity of the TA33, it might well have been that model.

There is no ground wave
propagation of horizontally polarized waves. Thus, a horizontally
polarized receiving antenna ignores much of the available noise.

There can be exceptions to this though. There is a horizontal "space
wave" and it can cause all kinds of noise problems. In fact, I have
had just as much noise problems with horizontal dipoles, as I have
with verticals. Much of the local noise here is power line noise.
The lines are horizontal in general, and do emit a horizontaly
polarized
space wave which can travel a fair piece. I've found at this qth,
polarization and noise don't always follow the expected norms.
I've had horizontal antennas that picked up horrible amounts of noise.
But....On the bright side...it does verify that they are working... :/

Here in the cement jungle, I think noise can be about any polarization
depending on the source. Some is vertical, but just as much is also
horizontal. Of course, being vertical can follow a true ground wave
type of propogation, I would expect vertical noise to travel farther
than horizontal if you exceeded the direct line of sight. MK

Hi Richard,

A reasonable guess indeed, given that the monopole with two radials is not too terribly different.

>The idea of a polyphase antenna is interesting but I don`t see what
>justifies its increased complexity, unless it happens to place nulls

Well, in phact the fases contribute to null philling - but not completely so.

>In that case, the elements would most likely be vertical to launch a decent
>ground wave.

Interesting lobes change, with it turned into an upside down Y (like the star for a Mercedes) the result is to pump the clouds to more effect. When turned to present a right side up Y, the result is distinctly more inclined towards the horizon, but still a better horizontal polarization performer than vertical (which is attended by many more variables related to ground and height, of course).

Asked something similar while ago but this time I will surely build the thing. So, I will put up a vertical over metal roof. Roof is 11 by 35 metres, 17m from ground, vertical will be 7m from one end of the roof, support (a fishing pole) will be 9.5m high. Feeder will be unbalanced open wire (173 ohms) described by K7JEB in this group.
And then autotuner. I want to operate on 30 and 17, 40 would be bonus, 20 optional. 80 would be very nice too......
Shortly, would like to have a compromise antenna for 80, 30, 17. Autotuner will do the work but why not try to make it bit easyer fot it. To get 80, i feel that i need to coil the wire around the fishing pole. If I would coil 20 metres, would feedpoint impedance be same (yes, not efficiency) as if wire would be stretched out? If not, should I coil more or less and by what margin? And what length for feedline? Minimum would be 8m. I guess I'd like to have some kind of "vertical G5RV". Did some modeling using 4nec2 but its like banging head against wall.. So, any educated guess/opinnion/suggestion will be most welcome. Otherwise I will cut everything random and, I'm afraid, result will be appropriate too..
Sorry for lenghty post.

Andrus

You can do that to get 80m, but you will degrade the performance
on the other bands. Probably the best way to get 80m and not
degrade the performance on the other bands is to use a high-Q
base loading coil that can be switched in for 80m and out for
the higher frequencies.

Then, by the criteria set in his question:
"Anyone know anything about this?",
you are unqualified to reply to his post -- and, should not have.

Dan,

As a couple of other fellers stated, I, too, am unconvinced that the
family of 3-el tribanders (the Mosely TA-33, the Cushcraft A3S, etc.)
are very much affected by the presense, or lack of a choke balun.
I've operated my CC A3S both ways and am unable to distinguish a smidgen
of difference.

For a multi-element monobander...., well .....

Just insure you've got a "50 ohm source" and a "50 ohm transmission line"
to feed your "50 ohm load" and you should be a happy operator. At
least it will work well enough to keep you On The Air, and keep
you off of usenet and out of rraa where publicly anguishing over your
concerns usually results in abuse by the resident stalkers.

I think Roy is referring to a T configuration rather than an upside-down L. The currents will balance in the T so wire size is limited by physical considerations rather than electrical. This is just another form of a capacity hat. The net result is to raise the radiation resistance.

Thank you Walt, my interest is both ferrite bead baluns and coax air core. I have searched the internet and found a lot of measurements of magnitude and phase angles for various configurations, unfortunately none of them appear to agree. I am hoping to come up with a definitive set of tables that the average guy can use.

The only things I know for sure is that no balun covers from DC to daylight, or even 1.8 to 30 Mhz.

I was thinking it might be solved with washers and steel wool. (Grin)

Fred, I'm afraid you're wrong.

Slide a sufficient number of ferrite beads over the coax line and it
will easily cover 1.8 to 30 MHz. Alternatively, wind sufficient turns
around a largish ferrite ring of the correct grade of material.

They are a ham radio dealer in Ohio.
Jetstream is their house brand.
I'm going to order some other items and I'm looking for opinions on
their coax. There isn't a review on eHam and Google hasn't turned up
anything beyond the catalog and spec sheet.

Reg is right, Fred, the W2DU balun with 50 #73 beads was designed to cover from 1.8 - 30 MHz. The series impedance along the outer conductor of the coax at 2.0 MHz is just over 750 ohms. If the antenna operating at 2.0 MHz is a half-wave dipole, half the dipole impedance at resonance will be around 35 ohms. The ratio 750/35 = 21.4, which gives an approximate isolation of the common-mode current of 26.6 dB below the current into half the dipole, which is more than adequate. If you want still more, make the balun with more than the original 50 beadss.

If you don't have a copy of Reflections you can find the balun data from my web page at www.w2du.com. See Chapter 21, page 21-8, for the graph that plots the resistance, reactance, and impedance of the outside surface of the coax in the W2DU balun vs frequency.

I am setting up my new Butternut HF9V ground mounted vertical on the side of my house. Right next to the antenna I have driven a ground rod that I will attach my antenna and radials to. The question I have is will it be OK to attach a ground wire from my shack to it too, or should I drive another ground rod that is separate for my shack only? If I drive another rod it will be about 8 feet away from my antennas ground rod. I have installed my vertical on a tilt over bracket I bought from Gap so I can hide the vertical when not in use because of restrictions in my subdivision.
Another question I have, and am concerned about is that my vertical will be about 25 feet away from my
neighbors Dish Network satellite dish. Is that going to be a problem for me and will TVI cause problems? If so what can I do
about it on my end? Thanks for your help and opinions.

In a tee type antenna, there will be considerable current at the junction of the horizontal and vertical wires. While it's unlikely that any wire strong enough to be used won't be able to handle the current from a heating standpoint, it is possible that using a wire on the small end of the range might result in noticeable loss. A quick run with a modeling program would show whether or not that might happen with a given set of dimensions.

One thing I should mention. If the horizontal portion is higher than about 0.2 wavelength, MININEC-type ground can be used for modeling either a T or L. The vertical wire is connected directly to ground, and ground loss can be inserted at the base as a resistive load. If the horizontal wire is much less than 0.2 wavelength high, the MININEC-type ground can still be used with reasonable accuracy only for the T type antenna. For an L type antenna where the horizontal wire is less than 0.2 wavelength high, a model has to use the High Accuracy ground model, with the ground system modeled as radial wires just above the ground.

>will be about 8 feet away from my antennas ground rod.

The National Electric Code, and thus most local building codes,
require that each building structure have only one "ground system".
In order to meet this requirement, all ground rods must be "bonded"
together with direct runs of heavy-gauge wire (6-gauge in most areas,
I believe).

The common 8' copper-plated-steel ground rods which are used for
lightning protection are good for that, but by themselves they don't
make terribly good RF grounds. You get a better RF ground by using a
number of shorter rods, a few feet or yards apart, bonded together
with heavy wire.

In your case, I'd drive in two ground rods - one as close as possible
to the shack (to which you ground your rig, with a wire that's as
short as possible), and one at the antenna. Bond them together with a
heavy copper wire, buried a few inches under the soil surface. This
should help meet the NEC bonding rule, and will also give you a better
RF ground than you'd get by running a ground wire all the way out to
the antenna. If you're feeling lavish, run some additional ground
wires outwards from your close-to-the-shack ground rod, and bury
'em... that'll help improve the quality of this RF ground somewhat.

>Another question I have, and am concerned about is that my vertical will be
>about 25 feet away from my
>neighbors Dish Network satellite dish. Is that going to be a problem for me
>and will TVI cause problems?

The satellite feed itself should be unaffected by the RF, I'd think -
the HF frequencies are far too low to be picked up by the dish's LNB.
I have an HF dipole located about 50' from our DirecTV dish, and
haven't seen any sign of interference.

You might end up with problems at the TV set itself, if your RF
"breaks in" to the TV's electronics via the antenna cable, or via the
power or speaker wiring. This is more likely to happen at higher
power levels, of course... keeping your transmissions below about 20
watts seems to help prevent most such RF breakin.

At your end, you might want to consider adding an auxiliary low-pass filter to your transmitter output, just to make sure you aren't transmitting harmonic content outside the HF bands. Check around your property for any loose, corroded metal junctions (e.g. old steel gutters and downspouts, fences, etc.), and if necessary clean 'em up and bond them - corroded junctions can act as rectifiers, and turn clean HF energy into a burst of harmonics that can cause TVI. These won't affect Dish Network reception, but could affect folks who are still picking up VHF channels via over-the-air antennas.

You might want to consider stocking up on a good-sized handful of clamp-on ferrite RF chokes. If your neighbors complain about TVI or RFI or telephone interference, give 'em the chokes and tell them to snap them onto the wiring of the affected appliances, as close as possible to the chassis (make several turns of wire through the ferrite if possible).

Legally, you are _not_ responsible for RFI problems if they're due to strong-signal overload/pickup and if your transmissions are "clean" (in-band, acceptably low harmonic content). However, it's often a very politically-wise and friendly thing to do, if you help affected neighbors eliminate such unwanted RF pickup... it might save you the trouble of having to deal with complaints from your neighborhood association, or even action re CC&Rs that your antenna may violate.

At some point a resonance will occur Reg. And while some particular combination may work - i.e. 7,427 ferrite beads along 841 feet of coax. I have found no practical balun that does the deed from 1.8 to 30.

Those that work well at 1.8 seem to end up with a resonance somewhere over 20 Mhz..

One solution may be ferrites to cover the low end in series with a solenoid coil for the high end.

Again, what I am looking for is a simple chart that says for a 10, 15, and 20 meter beam a solenoid of 8 turns on a 4 1/2" pvc coil form will provide the following impedances ...

Also most people will tell you that just looping the coils together will cause problems because of capacitance. I don't see that as a bad thing. Again I need to see data to confirm or discount my assumptions.

If nothing else it will be a fun learning exercise.

I ran into some problems with an all band no tuner antenna and started to try various combinations of beads recommended by the Gurus. While it worked OK on 160, 75 and 40, at 15 and10 meters the beads has insufficient impedance.

Ergo, I have mounted my steed and wooden lance in hand am off to fight the evil forces of unbalance.

http://www.bcdxc.org/balun_information.htm#Ed,%20WA2SRQ has some of
that sort of information, for a few specific combinations of turns,
diameter, and winding style.

>Also most people will tell you that just looping the coils together will
>cause problems because of capacitance. I don't see that as a bad thing.
>Again I need to see data to confirm or discount my assumptions.

What I have heard is that scramble-winding the turns tends to create a
higher distributed capacitance, and lowers the frequency at which the
balun exhibits self-resonance.

This appears to be born out by the table in the URL I gave above.
Compare the "8 turns, 6-5/8" columns for single-layer and bunched
windings. The single-layer coil has its peak impedance at 12 MHz.
The bunched-turn coil peaks somewhere between 6 and 7 MHz (highest
displayed impedance is at 6 but the phase is still very positive, so
I'm inferring a higher-impedance peak between 6 and 7 MHz).

The impedance of the bunched-turn coil seems to drop faster, on either
side of resonance, than that of the solenoid-would coil.

This suggests to me that the bunched-turn coil, measured and trimmed
carefully, might be a convenient choice for a low-HF monoband
antenna's choke, since it'd need fewer turns of coax to achieve a high
choking impedance. The solenoid-wound coil appears to have a somewhat
broader effective frequency range, and thus might be a better choice
for a 10/15/20 tribander.

> 20 Mhz..
>. . .

You're using the wrong kind of ferrite. Type 43, the most common type used for large cores, has a Q of 1 in the middle of the HF range. That is, the resistance equals the reactance at that frequency. So over the HF range a balun wound on a type 43 core with no air gap or by using beads W2DU-style looks basically like a resistor. You'd have to have extremely sensitive equipment to detect any resonance effects.

70 series ferrites have an even lower frequency Q=1 point, along with more impedance per turn squared, and that's what I mostly use. But a balun made with type 70 can sometimes get uncomfortably hot if you're running a kW.

R&L Electronics <http://randl.com>
They are a ham radio dealer in Ohio.
Jetstream is their house brand.
I'm going to order some other items and I'm looking for opinions on their coax. There isn't a review on eHam and Google hasn't turned up anything beyond the catalog and spec sheet.

Mike,
I've used R&L's jetstream 2013, the house version of 9913 Belden, without any problems. Compairs with the Belden cable and is much less expensive. Hopefully you will have the same luck I did.

Mark Keith, NM5K wrote:
"I`ve had horizontal antennas that picked up horrible amounts of noise."

Yes, the protectection comes from noise beyond the line of sight range
but not so far away as to require aky wave propagation.

Propagation is a function of frequency. Below 100 KHz, gtound waves are
little affected by the earth`s attenuation and the sky wave is reflected
with little loss by the ionosphere. Waves travel up to 600 miles with
little perturbation from the time of day, season, or year, but at
greater distances, low frequency reception is better at night and in the
winter due to ionospheric changes affecting the reflected signal.. On a
yearly basis, signal strength over long distances correspond with the
11-year sunspot cycle. Low frequency signal strength changes only slowly
without rapid fades which characterize high frequency operation.

At frequencies above 100 KHz but below 535 KHz, ground wave attenuation
is greater than at frequencies below 100 KHz. Daytime ionospheric losses
are very high. Daytime ground wave propagation is better at the lower
end of this frequency range and over soil of higher conductivity.
Signals may extend to several hundred miles, where noise levels in the
receiving location are low. Nighttime transmission to distant points is
possible due to ionospheric reflection. Dependable daytime reception in
the 100 to 535 KHz range is bad due to lack of ionospheric propagation
and high attenuation of the ground wave especially at the higher
frequency end of this band over poorly conductive earth and during the
summer months when there may be thunder storms producing static eithin
ground wave range..

At frequencies between 535 KHz and 1600 KHz, only the ground wave is
useful in the daytime beyond the line of sight, as the sky wave is
completely absorbed. The higher the frequency in this range, and the
poorer the earrth`s conductivity,, the greater the attenuation of the
ground wave. High powered transmitters at the lower frequencies in this
range reach 50 to 100 miles over high conductivity soil. This may be
pessimistic. I listen 24 hours to 50 KW KKYX in San Antonio which is 200
miles to my west satisfactorily. It broadcasts on 680 KHz. My receivers
are quite ordinary and use internal loop antennas. The earth is highly
conductive but there is no sea water in the path. At night, other
stations
produce low frequency carrier beats with KKYX causing undesirable
automatic volume control action. but KKYX`s sky wave is stronger than
its groundwave and its reception is still acceptable.. Radio Havana is
one of its competitors. I hear all about "El Comandante" at times.

Sky wave goes far in the 535 to 1600 KHz band. During Hurricane Carla in the 1960`s I listened to Dan Rather describe the storm blow by blow on KTRH, Houston`s 50 KW outlet, from Tierra del Fuego where I was working, and listening on a Hitachi pocket transistor portable radio with its built in loop antenna. The path is about 6000 miles long but mostly over the ocean. KTRH transmits on 740 KHz from the banks of Cedar Bayou. They have a 4-tower directionnal array with a North-South bias. Reception was good in Tierra fel Fuego as it is nearly at the Antarctic Circle and there are no thunder storms there. It is too cold. Groundwave extends hundreds of miles from KTRH, but not 6000 miles. My reception was shy wave using several hops.. Broadcast transmitters concentrate energy along the horizon so low elevation angles are favored.. This works well for sky wave DX, especially over the ocean.

Sky wave attenuation in the 535 to 1600 KHz band is about the same throughout the band, so nighttime coverage of broadcast stations in this range is almost independent of frequency, while daytime ground waves favor the lower frequencies. When I was a kid, I had a crystal set fixed tuned to KTRH which directly drove a loudspeaker, if I could find a sensitive spot on the galena. I lived almost in sight of the station.

At frequencies between 1600 KHz and 30 MHz, the ground wave attenuates so rapidly as to be usseless except over very short distances. Propagation is either line of sight or via ionospheric reflection or via tropospheric scattering. Frequencies above 30 MHz are often used for scattering ao that extremely high gain antennas are practical. Scatterihg often uses brute force to extend the range of signals beyond the line of sight.

Most long-distance short-wave communications result from ionnospheric reflection. In the frequency range of 1600 KHz to 30 MH, a band of frequencies can almost always be found that provides communications by sky wave over a path between two points on earth.

The maximum usable frequency depends on the distance between the points and ionospheric conditions. The minimum usable frequency depends on ionospheric conditions, effective radiated power, and the noise level at the receiver. Losses in the ionosphere increase with wavelength, so the frequency which gives the best signal is usually the maximum usable frequency. For communocations reliability, the maximum usable frequency is often discounted by 15% to provide an "Optimum Working Frequency".

Daytime DX requires a high frequency. Shorter paths require lower frequencies.

Typically 10 to 29 MHz during the day and 5 to 10 MHz, at night, are best for transmission over transoceanic distances (thousands of miles). Rember the Zenith portable? The best frequencies are usually higher during the day for long paths than they are at night

Optimum frequency increases with the length of the path up to the maximum distance for one-hop transmission, about 1200 to 2400 miles. Low elevation-angle radiation such as 5 to 15 degrees is usually most

desirable. Radiation below an angle of about 3.5 degrees may be absorbed by the earth near the transmitting antenna and wasted.

Frequencies above 30 MHz are usually not reflected by the ionosphere and provide only sporadic sky wave communications.

Best regards, Richard Harrison, KB5WZI

4614. Very happy with my 80 meter loop on higher bands

Newsgroup: rec.radio.amateur.antenna

Source record: 71431

I've got an 80 meter horizontal loop up around 50 feet in my backyard, fed with ladder line. It seems to work really well on 20 and 18 meters, no doubt has some decent gain over a dipole in some lobes. I push about 500 watts into it and work all kinds of DX with very good reports, even breaking pileups on 20 meters.

Would a 3 element yagi open up a new experience of antenna performance for me, in terms of forward gain? Sure seems convenient to have an antenna that doesn't require a tower and a rotator.

Thanks,

Chuck

Now that is interesting, Roy. I was going to put up a 160 m inverted L this summer. I am limited to only being able to go up about 45 feet, so I would need about another 90 feet horizontal.

Are you suggesting that it might be a better arrangement to go up the 45' and then put up the top "T"? If so, roughly how long should the top part of the T be (each side of center) to get me to 160? I'm guessing it may not be accomplished without some base loading...and that is what took me to the Inverted L in the first place...direct coax feed, albeit not a particularly good low angle radiator.

I am prepared to put down a radial field...but I want to stick with a simple vertical wire, either extended horizontally as an Inverted L or as you suggest, a T, if it can be done. I have about 100' either side of center available to construct the top part of the T. In either case, the top loading wires will need to be somewhat of the inverted v construction, as I don't have 45' high supports for each end.

Thanks for any thoughts you might have. I need to get something done before winter!

Source record: 71443

Carl,

Please don't use copper sulphate, it is illegal in most locals, gets into ground water and is poisonous . Another salt you might consider is sodium carbonate, "washing soda" it is pretty inexpensive but not as cheap as sodium chloride in the form of water softener salt.

4625. Material for Flexible Whip antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-24 03:45:54 UTC
From: David <david@orbitcoms.com>
Message-ID: <S3SOe.8590$FA3.4667@news-server.bigpond.net.au>
Source record: 71442
Cross-posted to: alt.ham-radio,aus.radio,rec.radio.amateur,rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc

I am looking for the Black (Nylon,Polythene ???) tubing around 6mm OD
and wall thickness of 1mm for construction of 900 MHz whip antenna.
It needs to be fairly rigid as it is glued to an SMA plug.

If anyone can advise what material is typically used and where I could
purchase
a reel of it (maybe it is even pressure tubing for pnuematics ?), it would
be much
appreciated. Australian source would be preferrable.

Thank in advance

Regards

David

Hi Chuck,

I have roughly 300 feet of 14 gauge insulated wire in a square horizontal loop at 28 feet above the yard here and use 4 foot sections of fiberglass camo netting supports at each corner guyed with para-cord . Work mainly MARS stations in the CONUS on 3 to 8 MHz frequencies using 100 watt Icom transceiver and AH-4 auto-tuner with ladder line feed. This antenna works very well in this application and I'm consistently reported as 'loudest station on the net', etc.

I've had lots of great DX contacts too. When you look at AZ-EL plots it has very sharp lobes at certain frequencies. Probably much better for DX at 50 feet. Delta loop is more omnidirectional and doesn't have as many sharp lobes.

Adding a tower, rotor and yagi would definitely open up much more DX. Have a 55 foot crank-up tower, rotor and 12 element log periodic project planned for this fall. For me, it's worth the effort. Should be much easier to contact friends that are currently in the Middle East.

73,
Mike ae6fl, AAM9ECS

For the performance/behaviour of a solenoid-wound coaxial choke,
download program SELFRES from website below.

Enter dimensions of the coil and the resonant frequency and impedance
versus frequency in a test circuit is calculated.

> Have you established that the pieces of the metal roof are electrically
> bonded?

well... I'm pretty sure it's electrically bonden. Pieces are shiny and
look like new. They overlap some. So, there's probably almost zero
resistance between them. Someday, wind blows away pulverized rust that
once was a roof but for now it'll make a great ground plane.

If I would get some low angle radiation on 80 then would'nt mind some performance degradation. But NEC shows that best gain would be at 90 degrees...
Probably could get 80 another way. Ok, but I still need to find "magical" antenna wire + feedline length combination. For that, probably 10 to 20 metres around that fishing pole. Could I model the vertical section as a straight (20m for example) and get same results as if the wire was coiled. Dont want to model helixes!

Mal,

I cannot see on the web page where they mention the material used for the
Whip Radome ?
They also don't seem to sell any tubing.

Can you advise me which page they advertise the tubing ?

Thanks

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-24 11:29:41 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <dehln5mt1@nwrdmz03.dmz.ncs.ea.ibs-infra.bt.com>
Source record: 71451

The performance of a coaxial choke inserted at the antenna end of the feedline cannot be properly studied without knowledge of the feedline's length in wavelengths and how the feedline is terminated at the transmitter end. No two systems are the same.

Choke performance depends on the condition of the system before the choke is inserted. The choking effect depends on the impedance seen by the choke looking into the outer conductor of the coaxial feedline.

The input impedance of the coaxial outer conductor depends on Zo, 400 to 550 ohms, of the single-wire line, its length in wavelengths, and on the very uncertain resistance of the ground connection at the transmitter end.

If the ground connection at the transmitter end is very low and the line is an odd number of 1/4-wavelengths there will be a very high impedance at the antenna end and longitudinal current will negligible. Insertion of the choke will have no effect.

If the line is a whole number of 1/2-wavelengths, with a low resistance ground the input impedance of the coaxial outer conductor will also be very low and longitudinal current in the line will be at a maximum. Insertion of the choke will be very effective.

With the usual random line length and on different bands, choke performance will always be completely random and unpredictable. Which explains the different opinions and arguments about whether a choke is necessary or not.

Program SELFRES3 models choke behaviour.

Try a gardening shop. Drip/micro spray irrigation uses pvc tubing that might
fit your requirement.
Don't forget to do a microwave oven test on the material because some black
plastics are carbon filled.

No. You might try modeling it with a number of lumped inductive
loads distributed over the length of the antenna.

> Dont want to model helixes!

Helixes make poor multi-band antennas because of self-resonance
effects. And remember, when a vertical is made longer than 5/8WL,
the take-off-angle increases possibly causing a lot of your radiated
energy to be lost in space.

To complicate things a little more, the common-mode current may
consist of standing waves. If the choke is installed at a current
minimum point, it may have little effect.

Lemme see.... At 1700 KHz I would say that the optimum filter would
be a piece of copper strap about 1/4" wide and 1/2" long placed right
across the output of the transmitter.

Stop back sometime and let us know how this works out.

Roy,
I built basically a loaded mobile antenna that went onto an airport
building in Raleigh, NC (about 60 feet) I was reluctant to build it because
I was afraid the people that I made it for (CAP) might not know how to do
the elevated radials. I was afraid they might come back on me. I reckon I am
one of those "trial and error" hams that has tried about everything in the
last 40 years and I am still learning. Anyhoo, BOY was I WRONG! They put
the thing on the air and it really puts out a good signal! None of us have
done any measurements or NEC modeling, etc. Frankly, I was surprised as I
had done very few vertical installations (well, I've got an AV8 vertical
all-bander). All I know is, at the 60-70 foot level with tuned radials, it
really sings!

==========

Dear Cec, It doesn't complicate things. It merely repeats what I have already said. When the line is an odd number of 1/4-waves long and there is an (albeit indeterminate) ground at the transmitter end, then there will be a high impedance at the choke (DUE TO STANDING WAVES) and the choke will then be wasting its time.

If you havn't, moons ago, already downloaded the program then do so and read the program notes. There are so many unknowns in it the results are only approximate but nevertheless sufficiently accurate for the intended purpose - which is just to demonstrate choke behaviour.

The only accurate result is the calculated-from-first-principles self-capacitance of the coil on which the impedance/frequency response depends.

I had checked calculations, years back, by winding many coils of various sizes and shapes, (one 7 feet long), with various numbers of turns and measuring the coils' self-resonant frequency over the HF band using hand-held instruments with coils suspended in free space from strings. I always knew the results would be useful at some time or other, never even dreaming about choke baluns.

Did I ever tell you that for several years I was Head of a Measurements Standards Laboratory which I personally set up from scratch and which was in the 2nd echelon from the British National Physical Laboratory. The NPL.

There were certain electrical parameters for which the laboratory was capable of making measurements more accurate than the NPL but for obvious political reasons it was not possible for the laboratory to claim such performance on calibration certificates.

Some time after I had left the position on promotion, the wicked Mrs Thatcher had the laboratory dismantled and sold it off in bits because it did not produce any immediate, short-term profits. She was a chemist who went into politics. Often I still wonder what happened to the oven-enclosed battery of 12 standard Western cells.

One day, if I can force myself to find the time, I may write my memoirs. I could tell you some amusing stories.

Yours, Reg, G4FGQ

[...]

>Your message was plenty clear, JC, I was just trying to be funny.

I suspect Walt to be well aware of mediterranean part of France and of
the reputation of mediterranean guys, including about antenna
performances they claim. ;-)

I must suppose that gain antennas is eventually varying with latitude,
but I don't know why, even after past 30 years of ham radio and
reading of W2DU, W7EL, W8JI, DJ2LR, VE2CV, G6XN publications.

Or I missed something : perhaps the answer is in EH principles,
Magnetic Balun, MaxCom Matcher, Isotron or Bazooka antennas, steel
wool baluns and so on ... In this case, sure I need some 40 years more
of hard job around aerials.

>But I do respect Dick Bird, he made great contributions to the field
>of dx antennas.

I do also respect Dick Bird. He made great contributions to the field
of dx antennas for numerous french newcomers issued from CB world
during the nineties and dreaming of the ultimate new big gun antenna
with minimum obstruction, work and expense.

in France, some of the last contributions of Dick were :
- Les antennes "supergain" (05-06/1990)
- L'antenne "ShoeBox" (02/1993)
- Beam "Trigonal" � Grand Gain (04/1993)
(in MEGAHERTZ Magazine.)

I apologize for my english expression.

And what I am saying is that exactly the same thing can happen NO
MATTER WHAT THE LENGTH OF THE FEEDLINE if the choke is located at
a current minimum point. I'm not arguing with you - just expanding
upon what you said.

Scarcely seems like a "Part 15" AM station under those conditions?

4645. Hooking up a Powered Antenna to a Boom Box...

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-24 19:22:27 UTC
From: dantan98@sbcglobal.net

Could someone please point me in the right direction?

I just purchased a Terk Q powered FM antenna to get better FM reception in my office. However, there is no means of hooking up the device to my antenna directly. The antenna has a hookup that looks like a coaxial connection, but without threading (cylinder with a post). Does anyone know of a way or can anyone come up with a way to hook the antenna to my "boom box", which has the standard telescoping antenna?

I appreciate any and all help you can provide.

Thank you.

Should I have one wire with two clips on either end? Also, should I
clip the powered antenna side to the post or to the cylinder?

Thanks.

First, you can't just wind X meters of wire in a coil and expect it to behave in any way like X meters of wire stretched out. It doesn't work that way, because the field from each turn couples to all the other turns, and the coupling is much different than for a straight wire. Resonance will depend on the diameter of the winding, the number of turns, the turn spacing, and the length of the winding (actually, only two of the last three, since any two determine the third). If the turns are uniformly spaced, a model of a straight wire of the diameter of the coil will give you about the same pattern shape (just slightly fatter than a dipole, ho hum), but it won't tell you anything about what the impedance of the helix will be. You will get some useful information from the straight-wire model, though. Make a note of the resistance the model shows. Then when you build your antenna, measure the resistance (which is the impedance at resonance). Divide the modeled resistance by the measured resistance and you'll have the efficiency. It might not make you happy.

I'm afraid you're going to have to find resonance ~shudder~ experimentally.

One additional comment. Don't worry about where NEC shows the best gain to be, unless you're using the antenna only for receiving. If using it for transmitting, pay attention only to what the gain is at the elevation angles of interest for your communication goals.

It might be. You might benefit from the radiation from the horizontal portion of an L, and you might not. But if it's quite low, the radiation will be mostly straight up, and a fair amount will be expended warming up the ground. Neither will occur with a T.

> If so, roughly how long should the top part of

I spend a lot of time learning about how antennas work, and try to pass the information along as best I can. But I find over and over again that most people don't have the ability to evaluate things in anything but a binary fashion -- everything has to be "good" or "bad" (or "good" and "evil"), "theory" or "experiment", "perfect" or "no good"; antennas either "work" or "don't work". So what I say is often interpreted as a statement that an antenna has to be perfect in order to work well, or to "work" at all -- whatever that means. But that's not at all what I'm saying. Let me try once again to clarify what I mean.

Just about anything will radiate, from a dummy load on up. But some antennas radiate a greater fraction of the applied power than others, and some radiate more in desired directions than others. What I try to do is to understand how they work so I can, if I want, optimize an antenna for a particular purpose. (And I don't necessarily always want to -- sometimes it's not worth the trouble.) But an antenna doesn't have to be optimum in order to talk to people. It doesn't even have to be optimum to get sixty-over-nine reports and break pileups. And it doesn't even have to be anywhere near optimum in order to provide you with many pleasant QSOs. You don't have to understand anything at all about how antennas work to put one up that will give you many hours of fine QSOs -- I must have put up hundreds without having a clue about how they really worked, and I worked plenty of stations. And I, like anyone else who's been around a few years, have a handful of great stories about some really crappy antenna that worked the rare DX. (I've even done it

with a crappy antenna and QRP.) What you have to understand is that you can work *more* stations, more reliably, if you do take the time and trouble (and if your yard and pocketbook will allow) to make your antenna more efficient and make it concentrate its radiation in the directions you want. But to a lot of people, it's not worth the time and trouble -- and that's fine.

Some people simply aren't interested in the technical aspects of the hobby, and would rather spend their time doing something other than learning about or even modeling antennas. There's nothing at all wrong with that. Those folks won't find many of my postings to be interesting, and won't read them, which is fine. And, like I did for a long time, they'll put up plenty of antennas that work well enough -- and even from time to time one that works exceptionally well. But I hope my postings will be useful to those people who are interested in learning more about antennas and/or who enjoy squeezing more performance out of them. And I learn from this, too!

Learning about antennas doesn't diminish your ability to experiment and successfully create working antennas. What it does is to give you more tools, so you can -- if you choose, but only if you choose -- make an antenna do what you want, rather than putting it up and settling for whatever it does.

well almost part 15.

4661. A choke balun is an impedance transformer.

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-25 07:29:19 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <dejs0elnm1@nwrdmz02.dmz.ncs.ea.ibs-infra.bt.com>
Source record: 71479

An unbalanced-to-balanced tuner is an over-complicated and unwieldy-to-use collection of components. It is usually operateable over only one or two adjacent bands. The only nice thing which can be said about it is that it looks good when outside of its box.

A choke balun can be inserted between a high-Zo balanced transmission line and the tuner to allow an ordinary, simple, unbalanced tuner to be used.

In the range 1.8 - 30 MHz, the balun consists of a relatively few turns of twin, flexible speaker cable wound on a ferrite ring about 2 inches in diameter. Or a pair of 18-gauge plastic-insulated wires can be wound alongside each other around the core. This is mechanically more convenient, more robust and less lossy than using coaxial cable with its very small-diameter inner conductor.

Furthermore, the twin-line balun, with its higher Zo impedance of roughly 120 ohms, has electrical advantages over the usually recommended 50-ohm coax. 120 ohms is intermediate in value between 450 and 600 ohms of the transmission line and the 50 ohms impedance to which it is eventually to be transformed by the tuner. This presents to the tuner a more manageable range of impedances it has to handle.

The line wound on the balun has to withstand the same high voltages which arise on the main transmission line with VSWR.

It is not generally appreciated that a choke balun behaves as an impedance transformer. Insofar as the tuner and transmitter are concerned it is a short length of 120-ohm line in tandem with the main balanced line which has a different impedance. The transformation ratio depends only on the length of line on the balun and on the operating frequency. It operates on the input impedance of the main line which can vary with frequency over a very wide range in a random manner. Therefore there is no fixed impedance transformation ratio between it is used. It can be considered indeterminate.

In general the transformation ratio increases linearly with frequency. To keep things under control during design the length of line on the balun should not exceed about 1/10th or 1/8th of a wavelength at the highest frequency of use. The propagation velocity on the balun line is about the same as when it is drawn out straight. At 30 MHz this limits line length to about 1 metre or 3 feet or preferably less.

So for the balun to be effective as a choke at 1.8 MHz the permeability of the ferrite material must be large enough to produce sufficient inductance with the number of turns on the core permitted

by the restriction on line length.

Here is another advantage of twin-line over coax because the propagation velocity on coax is much lower than twin line which further reduces available line length and also the possible number of turns.

Even at 30 MHz, loss in the balun is very small because of the short length of line and wire thickness. A small line loss in the core material does occur because of flux which leaks outside the immediate vicinity of the line into the ferrite core.

Most heating loss in the core is due to longitudinal current in the choke at the lowest operating frequency when, insofar as longitudinal current is concerned, the pair of wires behave as a single inductance-producing wire. But the power available from longitudinal currents is already lost from the antenna anyway. To mimise longitudinal current make sure there is sufficient inductance - which is the sole purpose.

For the design and peformance of a choke balun download program BALCHOKE from website below.

Hey all,

I was curious if you are aware of any new antenna developments /
techniques in regards to AM broadcasting. I'm specifically interested
in smaller AM antennas with high power ratings and a broadband response
between the AM channels.

I've already stumbled upon DLM from the University of Rhode Island,
Fractal Antennas from UCLA, EH Antennas from Ted Hart, Isotron, etc.

Thanks!

CD

Interestingly, you can make it a perfect circle by connecting the ends of
the 3 radiators with a conductor that forms a circle. ie a 3 phase halo. If
you look at the radiation pattern for this arrangement, or Reg's original
one in free space, the major gain is perpenticular to the plane of the
radiators, not in plane, although the effect is not very pronounced.

I've also skimmed through some CFA, Plasma Antennas, and DDRR stuff.
Out of these, I think Rob Vincen'ts DLM looked promising. I've read
through the test report for some of his antennas and they look
promising. However, I don't think he's tested his pieces on the lower
AM bands. As for the others, I'm not quite sure about them.

In your area of Clearwater FL, that shouldn't be a problem - what with all that seawater lapping at your ankles (metaphorically speaking, of course).

>I'm specifically interested

That is a contradiction in goals.

Then you should be warned that stumbling is par for the course.

Consult the archives.

Roy, W7EL wrote:
"First, you can`t just wind X meters of wire on a coil and expect it to behave in any way like X meters of wire stretched out."

Of course, Roy is right. Yet, the more wire wound coonsistently on a form, the more inductance and the lower its self resonant frequency.

My 19th edition of the "ARRL Antenna Book" offers some guidance in winding radial-mode helical antennas based on experimental results. It appears on page 6-26. It says that a 1/2-wavelength of wire wound with equal spacing between turns comes close to making a resonant 1/4-wave whip.

J.L. Davis, W5LIT (now SK) in 1949 made such an antenna to use on his new Ford, with a surplus PE-103 powering his mobile rig. The antenna was wound on a bamboo fishing pole. It had such a high-Q that when he modulated,a plasma broke out at the tip of the antenna. J.L. was an operator at KXYZ and KPRC which shared a transmitting tower. He made lots of contacts using the fishing pole antenna.

Best regards, Richard Harrison, KB5WZI

Hi,
I know nothing about electronics etc. My question is:

I have an old 12' dish that is no longer in use. Is it possible to use
that as a high gain FM antenna? I'm about 35 miles out of town, and
located in a low point so my FM reception is poor. This 12' dish is
stitting there rusting. What are the chances of removing the LNB and
getting some FM reception from it?
Any other uses for a 12' mesh dish? Astronomy? Radio Telescope?
At present I've got it pointed right at one of the neighbours houses
and it must be annoying..... :-)
Cheers

Do a Google search on CFA antennas. Touted to be the most fantastic antenna since sliced bread. You might also visit fractenna.com for another source.

It's too small to be of any use for FM broadcast band - diameter is only
about 1/10 of the wavelength.
Rather invest in a yagi or corner reflector for FM broadcast.

Won't get too much gain at ~100 MHz (FM radio band in the USA). Plus
you should have a line of sight view from you to the transmitting tower...

If it was solid, you could use it and a microphone to pick up sounds from
far away - like the ones they use on the sidelines at pro football games.
but being mesh - - I'm thinking a conversion to maybe a grill.

Hi Dan,

It would be far simpler to hit the "Open" button and select an already
existing example of an antenna and see where that goes.

In the main window, click Help, then Contents. This is the EZNEC manual.
Read the Getting Started section, and go through the "Test Drive"
tutorial it directs you to. That should get you started.

All I know is, at the 60-70 foot level with tuned radials, it
really sings!

They do. I've always preferred an elevated vs ground mount
vertical. At that height on 80m, you appx equal to a ground
mount system with 60+ radials, if they are using 3 or 4.
Also, more clear of surroundings, etc.. Your local ground/space
wave will usually be better. I bet it's good to dx at 2-3 AM...
I've also used the usual L's and T's on 160m. Like Roy mentioned,
which is better will depend on the angle needed. The T is better
for strict DX, but often the L can be better to regional stuff.
I'd have to double check, but I don't think adding the other
half of the "T" top really changes the resonant freq a whole lot
vs the L. IE: when using a "T", you will still need nearly a full 1/4
wave from the base to either end of the top horizontal section
if not loaded.
What can be handy for low banders, is nearly any dipole can be
loaded up as a T vertical, if you short the conductors. Doesn't
matter what type of feedline. Loading a 80m dipole as a T on
160m, is usually far better than trying to load the dipole as a
dipole...
If you don't short the feed together, but only feed one conductor,
you then have a quicky L...Thats one quick way to compare them on
different signals to see which is best at a given time. 160 is kinda
weird...Often an L will outdo a T early in the evening, but usually
later,
the T will be better, even on the same short paths. Would seem to
indicate the higher angles are less used later at night..
Sometimes I run a 80 meter turnstyle, and feed that as a vertical with
an "X" capacity hat... That made a pretty good vertical which usually
beat
the L late at night. BTW, the vertical part of both antennas are appx
40-45 ft or so.. So fairly equal in that regard.

4685. Best Antenna for Receiving - NEWBIE

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-26 08:56:55 UTC
From: Birderman <birderman@removespamhotmail.com>
Message-ID: <1125046611.272f62ab9287ee65fc91f507d9c1c2de@teranews>
Source record: 71502

Hi,

Being a Newbie, in West London, to this hobby of SWL, I am seeking advice on best antenna to use.

I have ICOM PCR1000 and Yaesu FRG100. At present I use a 25MHz-1300MHz (TANDY/RADIO SHACK) Discone for the ICOM and a long wire with HOWES ATU on the FRG. Both rigs used in first floor room so grounding is a problem as I would nead around 10m cable run to get to a ground rod, at moment connected to water pipe. The ICOM performs well with the Discone throughout its range, even on the HF. The longwire is not as long some mentioned on the websites/books, its around 8m long and slopes east/west direction, cannot install in any othe direction or increase its length. The FRG performs well but only seems to receive channels from the East and sometimes from west, channels North and South seem to be elusive. The broadcast bands work well, but HF Airband and Datamodes seem to be very weak and noisy.

Since my main interest is Airband and Datamodes I would like to be able to improve my reception of these.

So I hope answesrs to the following questions will help me in reolving the problems:
1/ I understand that Longwires can be directional so limit whats being received, so considering my available space would one of the vertical wide range give better alround performance with restrictions on direction.

2/ Are Dipoles directional as ?

3/ Do Dipoles need to be mounted horizontally ?

4/ Is it possible to have dipole with both elements parallel to each other or do they need the traditional arrangement of being opposite each other.

5/ Can the Dipole be made using wire with the Elements arranged in an inverted V formation ?

6/ Can Longwire be folded/bent round corners ?

7/ Is it possible to use several long wires in different directions connected to the rig simulatenously ?

Any help and suggestions in resolving the above will be most appreciated.
Regards
Birderman
West London, UK

I bought EZNEC +,v4 and enrolled in the ARRL antenna course. With my
many years of experience (bad & good!) I knew it was unlikely I would
really get much out of either....

It has turned into one of the best educational bargains I have ever
encountered. I am less than halfway through the course and find my
biggest problem is that I keep running off in all directions to check
out my past antenna failures.

My wounded ego is healing nicely and I am satisfied that I am no
antenna expert. I am a perpetual antenna student!

You might try rec.radio.amateur My solution to such a problem would be to buy the service manual. Problem with oscilloscopes is you often need a scope to fix a scope. What kind of problems are you getting?

I have no experience with this particular device, but have studied the specifications available on the web. From the point of view of a low cost, single port, network analyzer it does seem to be much better than any of the others available, such as the MFJ units. As with all the units there does not seem to be any accuracy specified. I would have liked to see the ability to measure < 5 ohms, and go below 1 MHz. A Smith Chart display would also have been very useful.

I think it is a good deal and would recommend it. Problem is, for the moment, they do not seem to be available.

Regard,

Frank

Hi OM,

Your 8 meter "long wire" is long only for frequencies above roughly
20MHz. You neglect to offer how high it is, but in all probability,
it is lower than a quarter wavelength for mid-HF. In this regard (and
being unbalanced) it is probably quite omni-directional.

>so considering my available space would one of the vertical
>wide range give better alround performance with restrictions on direction.

No.

> 2/ Are Dipoles directional as ?

As what? the long wire? Same kind of problem of being low to the
ground. You might get some directionality gain from having a balanced
antenna - being able to HEAR the difference is another matter (and
more to the point, you would want to null noise sources which might be
a possibility).

> 3/ Do Dipoles need to be mounted horizontally ?

All depends on your goals. Otherwise, no, as long as you can make a
right angle connection at the midpoint (or snake the drive line up
through the interior of the lower section - research a "sleeve
dipole").

> 4/ Is it possible to have dipole with both elements parallel to
>each other or do they need the traditional arrangement of being opposite
>each other.

This anticipates your question about a V antenna:

> 5/ Can the Dipole be made using wire with the Elements arranged
>in an inverted V formation ?

Yes, such an antenna is so named.

> 6/ Can Longwire be folded/bent round corners ?

Yes, but as you are putting this to wideband use, such elaborations do
not really contribute to the whole.

> 7/ Is it possible to use several long wires in different
>directions connected to the rig simulatenously ?

Yes. This is called a "fan dipole" and the wires are usually cut for
different bands.

Hi Slim,

First, your question is not at all "stupid" for someone with a non-electronic background.

Second, I apologize for some of the members of this NG who take the time to post replies, but then offer only snide remarks and insults to the person with the question.

Now to your question... Your dish--big as it is--is not big enough to make an effective reflector for the broadcast FM band. Your best bet for fringe FM reception would be a high-gain FM-band Yagi, which you could probably locate with a net search.

You might be able to have some fun with your big dish by putting a UHF-TV bowtie or loop at the feet point, and pointing it at your local sources of UHF-TV broadcasts (if any).

BTW, if you subscribe to satellite TV out there, the satellite services have lots of nice music channels available.

Good luck, Ed

Just a few comments..

- When receiving only the important part is to have a good signal to noise ratio. HF is always pretty noisy and pretty well never below the receiver noise floor. Antenna design for HF RX needs to consider reducing noise as well as increasing signal.

- A dipole has a maximum response at right angles to the wire. This ONLY applies if the dipole is a half wavelength long and is centre fed. (Some pattern skewing will normally be evident with an end fed dipole in the direction away from the feedpoint) A piece of wire one wavelength long will tend to exhibit maximum responses at about 45 degrees to the wire. ie there will be 4 lobes in the horizontal plane. You see then that it isnt simple to give a straight answer on this. Whatever frequency you choose for the particular wire length you will get varying patterns. You can of course cut the antenna for the band of interest.

- Vertical antennas tend to be noisier than horizontal antennas. (ie they pick up more local man made noise)

- There is no reason why you cant mount a dipole vertically or even diagonally. It is important though to have the feed line at right angles to the wire for some length. The pattern is of course affected by this orientation. When it is vertical it will tend to radiate equally in all (horiz) directions. You should also consider the ground as a kind of lossy reflector.

- You might like to look at a folded dipole antenna. I have heard the claim that they are less noisy than a single wire dipole. Suggest you have a look at Mr Cebik's TFDP on http://www.cebik.com/wire/wbfd.html

- Two parallel elements will generally speaking look like a continuation of the transmission line and not radiate/receive as effectively. It depends on the spacing though. You can tune the distance apart so that some gain in a particular direction/directions will occur. I would suggest you keep away from this for general HF use.

- A right angled dipole (lookup "Inverted V") with the feedpoint at the highest point is a valid design. I'll admit I havent researched it but anecdotal comments to me in the past say it works much better than a dipole with a lower feedpoint but same average height.

- Yes a long wire can be bent. It is surprising (to me) how much it doesnt affect directivity. (Assuming the bends arent too great!) You may wish to model this kind of thing (and other antenna designs) using Eznec/4NEC2 etc. Its all very fascinating.

- A wire in a horizontal V shape will tend to radiate/receive more in the direction of the open end of the V. Once again though for varying frequencies/lengths this behaviour will be variable.

- Yes you can connect more than one wire to the RX at one time. There will of course be interaction depending on their length and usage frequency. You may get a useful directive pattern or something that is useless.

- If you want to monitor a specific spot frequency on HF I would suggest a single quad loop.

- If you really want to fiddle with a sharply tuned low noise antenna have a look at magnetic loops. They can usually be made to cover a 2:1 (or more) freq range and maybe what you are after for RX only purposes. The signal strength will be lower than (say) a dipole but the signal to noise will be much greater. (anecdotal knowledge)

- Make sure your station grounding is good. For noise reduction as well as safety. You may also want to check your house appliances for noise creation and suppress them. Keep in mind that at the distance you currently have to ground that looks like a 1/4 wave on about 7Mhz, 3/4 on 21Mhz etc and thus a high impedence path. ie the noise volts in the system (at those freqs) wont flow well to ground through this path. In fact any other noise that exists on the water pipe ground from other sources may interfere. Whether running a separate piece of braid/wire will help is an unknown. It depends on a number of variables, but it cant however hurt to try. Also ensure that power and other boxes connected (eg a computer for digi modes) are single point earthed and isolated accordingly. (eg if you are using a soundcard to demodulate digi signals make sure there is (say) transformer coupling between the radio and computer)

Hope this is helpful. My suggestion would be a WBFB as big as will fit in your yard, maybe bending some of it to fit. Also keep the feedpoint high (ie inverted V construction) Also run a thick braid earth from your station to a seperate ground stake. Read up on this espcially in the area of grounding RF rather than just safety issues. Then bond that stake to your electrical ground as well (ie outside the house)

4693. Blowing up a VLF converter

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-26 17:03:06 UTC
From: Ken Bessler <kg0wx@NOSPAMyahoo.com>
Message-ID: <fXHPe.5152$ct5.5069@fed1read04>
Source record: 71509

I was looking for an antenna for my LF/VLF converter.
The converter is from Jakson Harbor Press and uses a
SA602 chip to convert 10-400 khz up to 14.010-14.400.
It has 2 five pole L.P. filters (cutoff @ 500khz).

For $12, it can't be beat. Anyways, I've got it running
and everything that should be grounded is grounded. I've
got a antenna lead with an alligator clip on it and I'm
probing around, listening to WWVB. I try my 40m inverted
V (fed with ladder line & coax). I get a pretty good signal
on the "hot" side (the side that connects to the center of my
coax) but also I get the same signal from the ground side so
I left it there.

The path for the 40m antenna is radio/coax/coax coil/ladderline/
antenna. The converter is hooked to the junction where
the coil transitions to the ladder line. It's just a pl-259 with one
side of the ladder line going into the center pin and the other side
soldered to the shell. I figure I'll just go out and unhook the
converter's antenna clip when I use the 40m antenna.

Getting gutsy, I decided to see what would happen if I didn't
unhook the converter and transmitted into the 40m antenna
I tried 1/2 watt - no damage. I then tried different power levels
finally ending up with a 15.2w CW carrier. No damage!

I thought I'd blow my little converter. Anyone care to educate
me as to why it didn't blow? Would it have blown up if I had
hooked to the other side of the ladder line? Did the 2 five pole
low pass filters save it?

I'll bet if you put a little microphone at the focal point, you could hear things a long way away!

You could also line it with aluminum foil and use it as a solar oven. Be careful, though! The focal point will get very, VERY hot. And bright.

>My money's on the filter.

Yeah, there would be quite a lot of attenuation... five poles, and the
40-meter signal is about four octaves above the filter's nominal cutoff.

I thought that the converter might possibly include a set of
anti-parallel diodes between the filter and the SA604 to provide some
additional strong-signal protection, but I don't see any. So, it must
be that the filter attenuation was sufficient to keep the SA602 input
levels below the danger threshold. I seem to recall that these little
Gilbert-cell active mixers are reasonably rugged.

In looking at the schematic, I do see one thing which concerns me.
The filter is a pi configuration, with a .01 uF cap to ground at
either end. The cap at the antenna end of the filter (C4) would tend
to shunt a lot of the 40-meter signal to ground, with L1 blocking much
of the rest.

Seems to me that there could be two bad effects from having this
circuit shunted across the antenna when the 40-meter transmitter is
keyed up. For one thing, it could present a low impedance at its
attachment point (depending on the length of the feedline from the
upconverter to the attachment) and might adversely affect the
transmitter. For another thing, if there's a significant amount of RF
power getting to the front of the filter, it'll be shunted to ground
through C4 (a little monolithic ceramic by the look of it) and losses
in C4 might be sufficiently high to cook it and let all of its magic
smoke out.

If C4 does pop, the converter would still work, but there'd be one
less pole of low-pass filtration.

It might not be a bad idea for the OP to check C4 to see if it shows
signs of overheating, and perhaps consider adding another inductor
between the antenna terminal and the C4/L1 junction. This would
convert the filter from a two-Pi to a three-L configuration, and
increase its antenna-side impedance at HF.

As the filter represents a very high impedance above 500 Khz it should have protected the converter.

"I was looking for an antenna for my LF/VLF converter."

Over the 10-400 KHz frequency range, there are propagation variations between night and day. A tuned loop antenna of the type often used in MW broadcast radios also works in other frequency ranges including your converter input.

The tuned loop is small in terms of wavelength, yet it can improve signal to noise ratio from its frequency selectivity and from its directional characteristics. It can be an air-core type or be wound on a ferrite rod.

I won`t speculate why ken hasn`t destroyed his converter with his HF transmitter.

Best regards, Richard Harrison, KB5WZI

More like one wavelength: it's a bit over 3 meters. Still, as you
say, it's too small.

Elevation of the antenna will do more good than anything else, if
you're in a bit of a low spot. Pick an FM antenna with some gain
(Yagi, for example) and get it up as high as you reasonably can. It's
a lot easier to get an FM Yagi up a few tens of feet than it is to get
a 12 foot dish up that high!

Cheers,
Tom

I can't find anything other than a price and the boom length for this
antenna on Force 12's web site. I can't imagine why they would sell
this in the first place. Well, actually I can imagine, but it's not
because it makes any sense performance wise.

Build any decent modern design Yagi for two meters and forget even
using the other thing.

Thanks everyone for the advice - I did check for overheating
and I did check to see if the addition of the converter changed
either SWR or performance of my dipole. Seems OK so far.

Thanks for the education!

I've been on 6,2 etc for a long time, and would never have spent that kind of money for that low gain. I would say you need to put up whatever you need for 10, a decent 12' long 4 element for 6 and whatever you can support on 2. And use 3 feedlines. You will be much better off.

If you need specifics, please feel free to email me, I have decent plans for 10, 6, 222, and 432. On 2 it's best just to buy, there is so much competition that it's not worth building.

I disassembled my CT-3 trap (20/30 meters) and found absolutely nothing wrong with it, no carbon, no wetness, no burns and electrically connected wires. However, is there supposed to be a capacitor in there, (this is the older one), just the plastic coil forms with the two rods and properly riveted wire ends. Is the capacitor formed by the spacing of the two inner tubes. I replaced the trap with the newer version (I think - no center dimples, but black screws in the center). Cushcraft tech support states the traps were redesigned and are not interchangable unless you change CT-2 also, and change the spacing between the traps. (so why didn't they rename them (CT-3R), so now that I put the new trap in place, I still cannot transmit on 20, 30, or 40 meters (infinite SWR on built in tuner. Of coursec the spacing between the traps changed, due to the redesign, so I guess I'll have to lower the antenna down again and reinstall the original trap. If not the trap, then is there anything band specific in the matching network?

I believe the capacitor is the capacitance between the inner tube(s) and the outer tube. I found on mine that the connections at the ends of the coils in the traps corrode and then make a poor connection to the tubes. IIRC, they're riveted so I drilled out the rivets and replaced them with sheet metal screws. I also applied some anti oxidation paste meant for aluminum wiring...I got it at Lowe's. That seemed to help. You might check all aluminum-to-aluminum joints and and connections and clean them and apply the paste. It seems to help mine to do that periodically. You might also check inside the box. A close lightning strike a few years back wrought havoc on the matching box on mine.

The R7000 is definitely not Cushcraft's best piece of work. It has been a PITA ever since I bought it several years ago from the estate of a SK who belonged to our club. The 14AVQ I bought 35 years ago was a lot better antenna, as was the Butternut I had before the 7000.

You wouldn't happen to be the guy who bought the trap from K0FL, are you? I bought the box & other two traps...

Yes -- the capacitance between the inner rod and the outer form a variable
(or at least adjustable) cap, just like a 'piston trimmer'. This is used
to bring the trap to resonance. Before you spend
a lot make sure the connections at the end of the coils, as Mark suggested,
are good. This is a simple fix and will save a lot of money and grief.

100 foot of wire on 1700Khz is not a correct length antenna. It is unlikely
that your "part 15" device is matched to the new antenna, and may be worse
than the legal antenna that came with it.

You did not mention what you were using as RF ground.

PR:

Explore 1/2 wave antennas, you can load then with an inductance(s) to achieve the 1/2 wave electrical length, and they will work against a minimal counterpoise (chain fence, spare travel trailer you have parked around, metal shed, etc, etc....)

Long, long ago I ran a pirate am broadcast station using an old 50 ft. tv mast with loading coils and a heavily modified gamma match which used loading coils in its construction, was able to be heard for over 100 miles in the most favorable direction running 100+ watts though an old military transmitter... back then there were many pirate stations around...

Cross-posted to: alt.ham-radio.vhf-uhf,rec.radio.amateur.antenna,rec.radio.swap

1-DiamondX510MA (UHF connector)

The Diamond X510NA was designed for strength and performance and is
pre-tuned to achieve maximum gain in both the 2m and 70cm amateur bands.
(2m: 3 x 5/8 and 70cm: 8 x 5/8). It has a 3 section fiberglass radome with
overlapping outer shells for added strength. It comes with stainless steel
mounting hardware and radials and strong-waterproof joint couplings.

X510NA Specifications
Frequency: 2M/70CM (144-148 and 440-450 MHz)
Gain: 8.3/11.7 dB
Power: 200 watts
Connector: N
Height: 17.2 feet
Weight: 5 Lbs.
Wind Rating: 90 MPH
We also carry the Diamond X510M which is the same antenna, but with an UHF
(SO239) connector instead of an N connector.

Universal Radio price $188.95.00 new.

$115.00 for pickup or meeting in Se, Pa. only.

I played with it a bit and found that converting it to a T from an L
actually reduced the overall gain at 30 deg elevation and did not improve it
below that. I ended up with 73' on each side of the center for the T,
slightly inverted. In fact, I took the inverted L in one of my files
(already constructed) and just added the 2nd wire. I, did, of course shorten
the vertical section to the 42' that I have available.

It did eliminate the overhead radiation, but did not significantly improve
the low angle (which seems impossible), but I'll play some more. So far, it
looks like the Inverted L is the better choice, even for more power at lower
launch angles than the "T". (It is also easier to construct...for a quick
throw it up antenna, you only need a long piece of wire and an insulator at
the top, pullling as much wire as you can get to go vertical and stretching
out the rest.) Then, the real work comes, putting down a good radial field
before the frost.

Thanks for the tip. 73

I found the error, I had to fix two conditions that I had changed in the model:

Copper wire (for loss)
Ground characteristics

Now that both antennas have the same conditions, the T has ever so slightly better gain at 20 degrees than the Inverted L. Not enough to bother with the increased complexity, and the input Z is now down around 5 ohms for the T and 8 ohms for the L.

Now, is it worth matching the 8 ohms up to 50 at the feedpoint, or just using the tuner in the shack to take care of it? (coax feed, LMR-400, about 50')

A 187 foot vertical will suit your needs much better.

Add 120 300 foot long radials around the base of the antenna in a fanned
out configuration and we will know you are really serious!

Dear Dave Platt - AE6EO:
Thanks. I should have thought of that.
Back when Navy VLF stations were still using CW, one could receive great practice by listening. I used a crystal oscillator and a simple filter to modulate the oscillator with VLF.

Since you are talking about 50 Ohms I assume you are talking about a transmission line. If that is the case you should definitely match the feedline to antenna at the antenna feed point. Any attempt to match the feedline with a tuner in the shack only turns the whole feedline into part of the antenna system. By doing that you have lost any good work in building the antenna.

Don't do it. For $100 - 150 you can buy a 2 meter antenna that will
outperform two stacked 224s. I have a CushCraft 10 element. People sneer at
CC, but it works well. If you operate 6 meter SSB at all, I would upgrade
that next. Unless you get something big, the 4 element HyGain is good,
supposedly better than the CushCraft 5 el. If you ever get a real tribander,
avoid anything that has "Junior"as part of the name.

Why is it definite? What is the loss in 50 ft. of LMR-400 at the
frequency of interest when the SWR is 50/8 = 6.25:1?

> Any attempt to match the
> feedline with a tuner in the shack only turns the whole feedline into

Simply not true if the currents remain differentially balanced.
SWR doesn't cause feedline radiation.

If you would go here:

http://www.qsl.net/ac6la/tldetails.html

download the program and enter your load Z and 50' of LMR400 @ 3.5
MHz, you would immediately see the answer to your question.

If the 8 ohm is real (j=0) then the total loss is all of 0.4 dB and if
the line is 50' long, the resulting input Z is easily matched with low
loss.

The feedline is -always- part of the antenna system. If it troubles
you to think about matching in the shack, just think of the
transmission line as part of a matching network located at the
feedpoint. In other words, the feedpoint network is comprised of 50'
of coax and coupla LCs in a box. This network then connects to the
transmitter through a non-resonant (flat) coax line.

Let's take the case of a 50 Ohm line and some mismatched antenna. The result is a combination other then 50 Ohm with most likely a zero complex component. All a tuner does is match 50 Ohm at the radio to the complex impedance presented to it at the source of the line.

That the only place with 50 Ohms and zero inductance in the line - antenna system. The combination of cable and antenna presents something other then R = 50 ohms 0 reactance and the the transmission line see discontinuities. The result is it radiates.

I am not sure what you mean by -always-. If you mean there is no such thing as a perfect coax line then your statement is true but does not add any real value. If you mean by -always- the feedline is a significant component in the antenna system then I would have to disagree. When operated at their design point coax transmission lines do not radiate and are not part of the radiating "antenna system".

Coax is designed to work in a specific environment as a transmission line. These transmission lines are designed not to radiate. When transmission lines are operated significantly outside their design range the radiate. Adding a tuner to one end only controls the characteristics at that point. It does not 'clean up' the mismatchs.

Ok, I need teaching here. Why would the loss change? The loss on the line is forced to what happens at the nominal 50 ohms doesn't it? The SWR shouldn't be able to change it unless the voltage limits are hit I would think. I need an explanation of why it wouldn't be so.

Thanks.

An antenna tuner or transmatch, if you prefer, doesn't radiate and is
part of an antenna system. the fact that a transmission line radiates
or not doesn't mean it isn't part of the system.

If the currents are balanced, a 50 ohm transmission line seeing
something other than a 50 ohm load does NOT cause it to radiate.
If a 50 ohm unbalanced transmission line sees a 50 ohm balanced
load and common-mode currents flow on the outside of the coax,
it will usually result in radiation from the feedline. Simply
knowing the magnitude of the feedpoint impedance doesn't tell us
anything about feedline radiation.

The loss specified on transmission line charts are usually matched-line
losses (SWR=1:1). When the SWR is higher than 1:1, additional losses
appear due to the higher SWR. There's a chart in my ARRL Handbook that
gives those additional losses. The matched-line loss for 50 ft. of LMR-400
at 3.5 MHz is about 0.1 dB. Wes calculated the total loss at 0.4 dB but I
think that must have been for 100 ft. of LMR-400 at 3.5 MHz with an
SWR of 6.25:1.

The higher SWR causes additional losses because the maximum current and
maximum voltage is higher for the same power delivered to the load than
for the matched-line case.

Dan, I have just run a NEC 2 model of your antenna. I have used the Sommerfeld/Norton ground, with average parameters of: Er = 13, and Sigma = 5 S/m. The top of the antenna is at 18 ft, and the base at 3 ft. I have twelve 40 ft radials, spaced at 30 deg, and within the limitations of NEC 2, placed them at 3" above ground. The first 5 ft of the radials drops from 3 ft to 3" at an angle of 45 deg. The monopole is center loaded with an inductor of Q = 450. The model has 640 (6") segments and takes 3 minutes to run (3.5 - 4.0 MHz in 50 kHz increments). What I notice is that I need 92 uH to resonate at 3.9 MHz. The input impedance is 12 ohms. I used a lumped element model for the inductor. I may try a physical helix later. These data do not seem to agree with your measured results. NEC 2, with the Sommerfeld/Norton ground solution, is supposed to give a reasonable result with wires at > 10^(-3) wavelengths above ground (Basic Antenna Modeling, Cebik p. 15-16 Nittany Scientific).

Gain and take-off angle are excellent, with max gain of -3 dBi at 28 deg. elevation. The lower 3 dB point (8 deg elevation) gain is -6.6 dBi. The NEC output file indicates an antenna efficiency of 54%. A free space model shows an input impedance of 8 ohms, so your ground losses are not significant (At least with my model).

Apart from adding horizontal wires, in "T" or inverted "L" fashion, I doubt any antenna you could put up would match its performance at distances over 500 miles.

With 100 ft of LMR 400 the additional loss is about 0.45 dB. I would be very interested to know if anybody has any ideas why my calculations appear to be different from the measurements.

Regards,

Frank

>system".

Well, now, we've just morphed "antenna system" to "radiating antenna
system."

But never mind, nothing's changed, you're still all wet. Of course
the feedline is a component in the antenna system regardless of
whether it radiates or not. BTW the line can be perfectly matched and
radiate or it can be highly mismatched and not radiate.

>
>Coax is designed to work in a specific environment as a transmission line. These
>transmission lines are designed not to radiate. When transmission lines are
>operated significantly outside their design range the(y) radiate.

Squeak squeak---squeak squeak---squeak squeak, there I just screwed a
tee connector on the end of a run of 50 ohm coax and on the tee I
screwed on two 50 ohm loads. The line is now terminated in 25 ohm
making the SWR 2:1. 'Splain to me how well this line, "operating
outside its design range", radiates.

If that's not "significantly" far enough outside the "design range"
then allow me to remove the loads, add two more tees and terminate
them with four 50 ohm loads, making the SWR 4:1. How well does the
line radiate now? Should I continue to 8:1 or are you convinced?

>Adding a tuner to
>one end only controls the characteristics at that point. It does not 'clean up'
>the mismatchs.

It can certainly "clean up" the mismatch at the input to the tuner,
which unless I've been deluding myself for 45 years or so, is the
point.

Surely you don't believe this do you? It is -much- more likely that
the impedance is reactive than not. At one (fundamental) frequency
the reactance is zero. At every other frequency it is reactive.

I have an HP-141T, with a full set of the plug-ins. Buying one of these on eBay may be risky, since so many analyzers get abused by incompetent users. I would demand a right-of-return guaranty, and better yet, a personal interface with the seller.

Technically, the 141 system is great, top-of-the-line gear for 1975. <g> But it has no automation to guide and help you, no FFT, no digital output, no way to archive data other than a Polaroid camera hood. (Actually, you can take a fairly decent digital camera picture of the display. And yes, there is an interface for an X/Y analog plotter, but who has one of those plotters anyway?) You might want to get a 141 for it's analog quality, and then do a digital interface project on your own.

Don't select an HP-4195A for a spectrum analyzer. It doesn't have the full SA capabilities, although it triples as a SA, network analyzer and an impedance analyzer. You might find it much more suited to be a NA (up to 500 MHz) than anything else. It does have a 3.5" floppy, but the format is HP LIF, not DOS, so the data is not very transportable. It has an IEEE-488 I/O, so you can interface it to a PC. It's also god-awful heavy!

An 8562A is sweet, because it is also a fine SA, and it will go up to 18 GHz, and then will interface with the HP-11970(?) microwave harmonic mixer series, to let you go up to 96 GHz or so. It's also a lot more portable; you can carry one for over 100 meters before your fingers get numb.

I had a Tek 49x at one time; I never liked it. Subjective, true. I'd take one for free.

I always considered the HP-859x series to be the cheaper descendants of the 856x series. Still, nice instruments, but maybe not yet cheap enough for retirees.

The HP-8566B was HP's grand killer SA, with the 8568 being the lesser capable sister. If you could find an 8566B at a price you could pay, that would be great. The pinnacle for 1987. You can carry an 856x about two feet.

Be aware that all of the instruments we have been talking about are full of proprietary modules that are no longer in the parts pipeline. The CRT's are a real problem; the only place to get another one is from a parts unit. (OK, maybe somebody has some new ones, in the box, right next to their pile of unbuilt Heathkits!) Although the HP units were all top commercial quality, something will eventually fail, and Radio Shack won't be much help. OTOH, a non-abused HP could easily outlive the average retiree. <g>

4750. Looking for help regarding satellie antennae

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-28 11:08:07 UTC
From: jonel@glenavon1.demon.co.uk
Message-ID: <c963h15004nq6salpmckavrmmmulvpmfnq@4ax.com>
Source record: 71416

II have recently purchased a satellite receiver (ASR WS201) and I am having little success in getting it connected. I don't know if this is the correct place to seek such help, but I'm giving it a try anyway.

I am located in East Anglia in the United Kingdom. According to the satellite location map I should be pointing south and low. I'm having no success in getting any signal at all and I would like to at least decide whether it is my equipment (in which case is it the antenna or the set) or is it a problem with the area I am in.

I have no experience with satellite stuff and I would be grateful for any pointers about simple tests that could be carried out, or at least where I could go for help. I have tried the home page for the AMI website but there are problems with that also (www.amisb.co)

Thanks

John L

Dan,
I appreciate your reply, but it is filled with misinformation. Consider reading some reference materials. The errors have been discussed in other responses to your post.

I don't mean to insult you for trying to help, but the information you provided is so incorrect, that I couldn't let it pass. I hope no one attempts to make use of what you said...it will only compound the error.

I asked simply is it worth it? (in terms of loss). Wes had the calculator software that showed the loss is insignificant, so it saves the work/complexity at the base of the antenna. Radiation from the feedline is not a function of mismatch. I'm surprised Reg didn't go apoplectic over that one.

The tuner in the shack will do the job nicely.

Source record: 71419

Hello all,
My station consisted of an Icom 706MKIIG, the AH-4 tuner and a 360ft loop at 60 feet. The tuner is mounted at the loop on the roof with about 100ft of coax to the rig.

I just purchased a Kenwood TS-870s with built in tuner. I'm running it on the same feedline and thru the unpowered AH-4. The built in tuner works fine and all seems good.

Question: I want to remove the AH-4 to go with my 706 for mobile/remote use. Would a 1:1 balun work in place of the AH-4 to connect the loop to the feedline? I work 15 thru 80 most of the time.

For the same amount of power delivered to the load, transmission
line losses increase with increasing SWR. For a Z0-matched system:
(PLoad = Pfor - Pref) As the load mismatch is increased, energy
reflected from the mismatched load increases and is re-reflected
back toward the load at the tuner Z0-match point. As the load
mismatch is increased, more energy is stored in the transmission
line during steady-state. This is indirect proof that reflected
energy waves actually exist.

Even grossly mismatched open wire transmission line does not radiate
significantly. For example a 66 ft length of 3" spaced, open wire line,
shorted at one end, radiates only 4 - 5% of the input power. 95% is
dissipated in the conductor losses.

Satellite dish aiming is very critical. You must know the precise position of the desired satellite, and then calculate the required azimuth and elevation for the dish. More than a degree or two off, and you will get nothing. Try http://www.satsig.net/ssazelm.htm There are many other sites, just Google "satellite dish aiming".

Hello, i have 40 nice ceramic insulators for wire antennas to sell.

They are about 16 cm long, have two holes to let wire pass through (about 5 mm max wire diameter allowed).

They have been made to work at HIGH voltages.

Photo here :

http://www.arifidenza.it/Public/data/ik5wqo/200582813302_P8280001-640x480.jpg

They're on Ebay here : http://search.ebay.it/_W0QQsassZrightrik

(they're in Italy, buyer pay spedition expenses)

Thank you,
73 de Riccardo IK5WQO

Sorry, I was just thinking about the subject of the thread, not
reading what you wrote.

>so the loss is even less. It doesn't look to me like it's worth doing anything more than
>tuning out the mismatch in the shack.

Exactly. As I said earlier, if it makes it easier on the someone's
(not you, you get it) conscience or ego they can think of the
transmission line as a bunch of distributed L and Cs (with a little R
thrown in) that are part of a tuner.

When they get this "tuner" to show 50 +j0, then they can call the
length of line between the "tuner" and the transmitter, the
"transmission line."

In your case, you have a low-loss line, so the "R" part is low and the
system is efficient.

Hi Dan,

I have run the program to determine the precise resonance. The parameters are as follows: Inductor 89.3 uH, and resonant at 3.92 MHz. I can send you a zipped NEC output text file. It is about 190 kB. Also the NEC code I used. You can plug in the appropriate data into an Excel spread sheet. If you need any specific graphical output I can it as a JPEG file. I used the default input source of 1 V peak, which accounts for the low power values in the output file. The E-field data is far field, normalized to 1 meter.

The inductor is described as a lumped element, complex impedance, of 4.9 + j2200 ohms. I arrived at this value based on your Q of 450, and just played around with the imaginary value to achieve resonance within the 75 meter band.

Let me know if I can send the above information to the address shown in your posting.

Regards,

Frank

Yes, I did buy the CT-3 trap from him. I would assume its the newer model (I have no way of knowing, except that it had black screws in the center of the trap instead of the dimples). Mine didn't come with the protective boot, but I had one from by 80 meter add-on I'll never install. Replaced the CT-3 and still have infinite SWR on 20/30 and 40 meters. Maybe its a problem with the auto-antenna tuner in the rig (Kenwood 570D) and not the antenna. There is different spacing when using the new traps 6" and 18" between CT-1 and 2 and CT-2 and 3, from the original 16" and 16" spacing. As mentioned, old trap was completely dry with no burn marks, loose connections or carbon buildup. Everybody mentionms drilling out the dimples, I just tapped the trap on the stoop pushing the forms inward, and just pulled them out. reinstalling them would probably require an awl is hard nail to exactly line up the endpoints.
According to the criptic Email from Cushcraft tech support, the traps are proabably not interchangable, unless a tuner is used? They were willing to sell me their R7000TFK for $112+ which proably contains a new CT-2 and new CT-3 and some tubing.

Wes,

As a starter, look at this site:

http://www.cbtricks.com/~ab7if/coax/coax.htm

When a transmission line is terminated in it's characteristic impedance there is no voltage or current reflection from the line. The electromagnetic fields continue to flow into the termination as if the line were infinitely long. When a mismatch of impedance occurs, reflected waves will be produced and they will interact with the incident waves. The total voltage and current on the line are no longer the result of a single traveling wave from the source to the load. Instead, it is the algebraic sum of two waves traveling in opposite directions. This interaction results in what is known as standing waves. The waves remain in fixed positions along the line while they vary in amplitude and polarity. A wave of any shape can be transmitted along the line without any change of waveshape or magnitude. Looking at the gif below, we see a line driven with a sine wave generator, terminated with a short circuit to maximize the reflection.

My first claim is a tuner at the source does not materially improve what is happening in the coax. That is a tuner does not recreate the condition above where the coax is functioning as a properly matched and terminated transmission line. All the tuner does is match the impedance at the coax source back to some known, usually 50 Ohm, value.

My second claim is when the mismatch condition at the coax destination, i.e. antenna that may result in significant radiation from the coax itself.

Hi John,

These things take a lot of patience and knowing where the satellite is
in the sky. "South and low" is not very distinctive, and there in the
UK you are not expected to aim at the horizon, but rather some 35-45
degrees above (which would be low, compared to directly overhead).
>

Perhaps because you are missing the full URL:
http://www.amisb.com/
rather, you need to go to:
http://www.worldspace.com/coveragemaps/antennaguide.html
an notice what they mean by low and South East instead (towards the
Sudan-Uganda-Congo).

If there is anything in the way, you won't get your signal.

Hi Dan,

As true as that may be, the results run the gamut from trivial to
considerable as has been already discussed in this thread.

>My second claim is when the mismatch condition at the coax destination, i.e.
>antenna that may result in significant radiation from the coax itself.

This mismatch could arise for any number of reasons, and not all
contribute to radiation from the coax. Wes has already demonstrated a
deliberate mismatch at the end of a cable that exhibits absolutely no
radiation from the coax. This is because he has contrived to contain
the fields from emerging and coupling to the outside of the coax
shield. You should be aware that the shield does support currents on
the inside and outside that are wholly unaffected by each other -
except at the drive point where the two conduction paths are joined.

When you drive a dipole with a coax, the exterior conductive path of
the shield (a separate circuit from the interior conductive path of
that same shield) is in parallel with one arm of the dipole. This
means you have a third radiator that has a length and termination that
is undefined. It is THAT radiator that both causes a higher SWR AND
radiation that is not a normal condition for an otherwise tuned
antenna. Given that the length of the line's external conductive
path, and its termination is largely undefined (unless you take great
care to both measure and characterize such issues), the occurrence of
mismatch and radiation is highly variable. Thus, anecdotal accounts
of antennas being poor or good when they are driven by a simple coax
are suspect (barring the reporter also supplying the conditions of the
external path).

To eliminate the effects of this third path, a choke is added to the
drive point. The purpose of the choke is to add impedance to this
path to reduce Common Mode current. Common Mode current is the
current that flows due to an unbalanced system (the unanticipated
third radiator does that in spades). It flows in two wire
transmission lines too when the unbalance occurs for other reasons

(and those are plentiful as well).

Hi John L

I suppose you know that the satellite is above central Africa. That means that the antenna needs to be able to have a clear view of that point about 22,300 miles above the equator in Central Africa. The antenna with that receiver is not extreemely directional. Set the antenna in the South East angle in the Low position.

Did you Google on Worldspace?

Jerry

>
>Dan

Well, Dan, responding to your second claim first, consider either of
two situations,
1) center-fed dipole, fed with open wire line, or
2) a center fed dipole, fed with coax with an efficient choke balun.
In either of these situations an impedance mismatch between the
feedline and the dipole will NOT cause radiation from the feedline.

And taking a look at the web site you referenced above, the writer is
professing to clear some misconceptions concerning transmission line
technique. However, although he does present some straight dope, he
is also further spreading some misconceptions concerning SWR.

As he stated, there is a lot of misunderstanding concerning the effect
of line length on the amplitude of the standing wave, but he continued
the incorrect information on the subject, rather than presenting a
correction.

The fact is, Dan, that with lossless line the SWR is NOT affected by
the line length--it remains constant along the entire length of the
line. And further, the ONLY affect of line length on SWR is line
attenuation, which causes the SWR at the input to be less than that at
the load.

If you believe everything you read in that reference, you've been
duped.

No matter what the voltages and currents are, if they are balanced,
the transmission line won't radiate (much). If the SWR is 100:1 and
the currents are balanced, the transmission won't radiate (much). If
the SWR is 1:1 and the currents are unbalanced, the feedline is likely
to radiate.

> My second claim is when the mismatch condition at the coax destination,
> i.e. antenna that may result in significant radiation from the coax itself.

Please understand it is not impedance mismatches that cause radiation
from the feedline. It is unbalance in the feedline currents that causes
feedline radiation. Current imbalance and impedance mismatches are not
necessarily related.

Current imbalance in a matched system can cause feedline radiation.

Impedance mismatches can exist with negligible feedline radiation.

I am certainly not the sharpest guy in this forum, however, I have
been a ham for almost 47 years and I've been working with antennas
from the beginning. I retired after 33+ years in the aerospace
business where a good deal of my work involved rf design,
measurements, failure analysis and the writing of specifications for
rf/microwave devices and assemblies. I regret having to even bring
this up, but it seems that you're willing accept something written on
a CB radio site as fact while ignoring anything you hear in this forum
from professionals in the field. Why is that?

This I've already proved to be wrong by example. Let me try one last time. Since antennas are reciprocal, you don't even need a transmitter. Connect any length of coax to your receiver input. Terminate the far end with a dummy load (50 ohm resistor). Tune around the bands. What do you hear? Nothing, if the coax is any good and the receiver and dummy load are well shielded. So I suppose this proves one of your claims, a matched line doesn't radiate.

Remove the dummy load and replace it with a short circuit. What do you hear now on this totally mismatched line that by your reckoning should radiate like crazy?

Jochen, The MP-1 is a short loaded vertical. The EZNEC file
"Vertical over real ground" will come close if you modify it to model
the MP-1.
The coil is modeled as a "load" placed at the proper spot on the
vertical. The inductive load should be large enough to cancel the Xc
the short vertical represents.
Eznec will tell you many parameters about the antenna. It will not
directly tell you that it will be poor on 80 and 40 meters due to
ground losses, and losses in the antenna. It should do OK on 20 meters
up.
Gary N4AST

4775. Diamond W8010 any ideas?

Smitty,

I have more questions than answers. The AH4 is designed to match a
single wire (whip) antenna working against ground as best I can
figure.

http://home.comcast.net/~hamlakemn//ah4/ah4.htm

You say your loop is at 60' but the tuner is on the roof at the loop.
Is the roof 60' high?

Is this a real closed loop? If so how is the tuner connected?

With more loop parameters known, maybe it could be modeled to
determine whether a balun will function okay and whether the mismatch
on the coax will be acceptable.

What kind of coax are you using?

The '870 is a fine radio...got one myself.

Responses already show this is untrue.

Radiation from the external coax surface comes from launching a signal
on that surface. Good coax does not let signals penetrate its shield.

A mismatch between a transmission line and its attached antenna affects
both transmitting and receiving from the antenna, but does not launch
signals on the outside of the coax.

A mismatched transmitting antenna does not accept all available power
incident upon it and reflects a portion back toward the sender depending
on how bad the mismatch is.

A mismatched receiving antenna has a source resistance (radiation
resistance) and may also have reactance. A conjugate match is needed for
maximum power transfer to the feedline. The mismatched antenna will
either not extract all the power available to it in the passing wave or
else reradiate more than 50%, (with full extraction, the minimum
possible reradiation is with a perfectly matched antenna). Consider a
short circuit across the antenna feedpoint. 100% of the energy extracted
by the antenna is reradiated. Consider an open circuit at the antenna
feedpoint. Little if any power is extracted from the wave sweeping the
receiving antenna.

The most power is received by a receiving antenna when its radiation
resistance is matched to the Zo of the feedline. In this case, 50% is
the best possible received carrier power in the receiver input. Nobody
tells the antenna it is a receiving antenna. It is a conductor carrying
a current, never mind where it came from, so it is going to radiate.
When matched resistances are involved in source (radiation resistance)
and load (Zo matched), the power is split 50-50 between source and load.
The radiation resistance, is the source resistance for the receiver
load, and it represents the reradiation from the reeiving atenna.

50% of the received power accepted by the load is the best possible
performance. Mismatch means less. Either less power accepted by the
antenna or more power reradiated by by the antenna.

A transmatch can make the feedline appear as a matching load at the
antenna junction for receiving. If matched for both transmitting and
receiving, all available power will be transmitted and received.

I was in Scotland a few weeks ago. I noticed many satellite dishes and was surprised at how low the elevation angles were. Most were nearly set horizontally. Some had dish feeds which were actually depressed below the horizontal. I concluded that their vertical beamwidts were deep enough to work anyway. I assumed that the users actually were getting a picture. I suspect that in Edinburg, you can start by setting the vertical angle with a carpenter`s level. It works that way with most terrestrial microwaves. In East Anglia, I suppose you are farther south and need some vertical elevation angle on your dish, but not much.

You can get your bearings with a fix on the north star, some accurate maps, and information on where the bird is parked in orbit.

Hello Wes,
The loop is setup on a large, flat roof of a local business, atop 15 ft masts. Building is a 4 story brick & wood building (built in1907). No steel. One end of the loop is attached to the output (+) of the AH4, other end of the loop is attached to the ground lug of the AH4. Coax is an RG-8U (I think Belden.) from the AH4 to the radio. You are correct about the AH4 being designed to tune a wire against ground, but this loop works fine. In the past, I also rigged up a dipole to the ah4 (450ohm ladder line (+ & -) to the dipole feedpoint) and it worked well too. It's a very nice tuner (coupler).

In my experience, three terminal rotators are wired wth common, ac one
direction, ac the other direction. The position is timed from one end.
I think the ac volts are around 14 volts.

No, what happens is one of the terminals, say #1, is common to two (or more) windings in the motor, the other two terminals, 2 and 3, are individual connections to the other end of the individual windings. To turn the rotor AC is applied to, say, terminal 2 and through a capacitor to 3 using 1 as the return. To change direction AC is applied to 3 directly and through the capacitor to 2. The value of the capacitor and the AC voltage depends on the motor, I used a C-M motor with a Kenpro KR-400 control box and other than not having any position indication it worked just fine. I've since upgraded the motor, the box puts out about 18 VAC to drive the motor, the capacitor is about 30 uF, 60 VDC. I don't remember the terminal numbers versus coils.

Your subject line raises thoughts of many people separated by a common
language.

The usual reason for using four radials of certain length is that they
are elevated and resonant. Multiple radials of different length are
often operated in parallel because it is thought that there is then a
set that is optimum for each band.

Anyone who has tried to operate multiple dipoles in parallel will know
that without heroic effort this is a false premise, nevertheless, the
practice continues.

When you bury them, the radials are no longer resonant (at least where
you think they are) and trying to use multiple sets is an even less
good idea. You should use lay as many radials as possible. A rule of
thumb would be to make them at least as long as the radiator is high.

Based on practical experience with elevated 4 square vertical arrays on 40 meters, I suspect that might be a 'grave' misteak! Chortle..

I've noticed that with the elevated 4 square arrays, actual connections between elements very much change the elements in the way they present to the feed lines. I'm talking about completely grounded vertical elements and feeding each element with gamma match techniques. Note that in the common 4 square vertical low band array configuration, the spacing between the towers is roughly a quarter wave apart. That defined, it's obvious that you can proceed away from any given vertical toward another in the aray and .. you either reach or can reach it with the tip of a radial from another element. Thus you have the possibility of actually connecting the elevated radial to an opposite element's actual tower. Remember, the towers are all grounded. Your feed operation as to the gamma match section is already bonded to the vertical tower at that elevation point for the elevated radials.

Not surprisingly, I've found that connection of these between tower spaces with a common wire between the towers on the elevated 4 square model DOES change the parameters required for gamma match dimensions and tuning a lot more than you might expect. Further, if you position the radials so that they extend so they don't 'aim' toward the opposite poles and toward the center, that also changes the practical match operations of the gamma match sections markedly as well.

Further, even if you cross connect the between towers chort-line distance. obiously extending the radials directly opposite away from the poles, and then move toward the center where the relay switch box is located, you'll find another interesting fact about this there.

Simply connecting those cross-array wires together at the relay box site also has major implications on the tuning of the gamma match sections for the towers. Recall that the 'connection' to the towers, in this case, also is the shield of the coax cable matching section which connects each element of the 4 square to the relay box at the middle of the array. If I just open up the ends of each radial from each element there where it reaches that center pole holding the relay box, I get very noticable changes on the whole array and matching differences.

I can see and verify it with my MFJ antenna analyzer. I don't have the drive and desire to spend the time doing the exact match distortion paper work to define this for publication or whatever. Part of the reason to use the gamma match technique was to minimize setup time for these arrays, at the same time I solidly ground each tower for lightning protection. That last is particularly important for elevated radial vertical arrays in my very person experience at my W5WQN low band site.

Based on the above, and the understanding that any given wire laying next to another wire, in any location free space or whatever, is mutually affected by the other wire, I'd think what you propose is likely to lead to a ..

grave error! ;)

Why would you want to spend the money and rent a trencher? Use it for a toy. If you have a lawn edger (if not borrow one) use that and cut a 2 to 4 inch gruve/s in your yard and lay your radial/s in them. In about a week they will fill in by themselves and you will never notice them. You don't need to bury them as deep as a trencher would dig.

Thanx for any responses.

I've got an HT and it's got a basic dual band 144 MHz/440 MHz antenna. It's about a meter long, which would be correct for the 144 MHz band.

What makes this antenna different from a 144 MHz (only) antenna?

Are there typically two conductors inside, with one 1 meter and one 35 cm? Or are the antennas typically just identical to a 144 MHz (only) antenna, and it just works at 3/4 wavelength at 70 cm?

As I understand it, a 3/4 wavelength whip should work reasonably well, being resonant and having a similar impedance to a 1/4 wavelength whip. Is this correct?

To be more to the point -- I've got a Kenwood D700A in my car. It has a built in duplexer, and one antenna jack. I've hooked it up to a 2 meter antenna on my roof, and it seems to work fine, both on 2m and 70cm. But I'm wondering if I'm risking ruining it ...

(I haven't put a SWR meter on it yet. I probably should.)

And what's so magic about 5/8 wave antennas? It's not even resonant, so obviously a matching network of some sort will be needed, but why 5/8? Why not 11/16? Or 3/4? Or something else?

==========
Paul,

When buried, even only shallow buried, radials become almost
non-resonant and their exact lengths, depth and thickness don't matter
very much.

What matters is the number of radials. The more radials there are the
better. However there is a law of diminishing returns and after 10 or
20 have been laid, depending on soil resistivity, not much happens.

But to bury a number of radials close to each other in a common trench
constitutes only ONE thick radial. With 4 trenches you have only 4
radials. They behave better when wires are uniformly, radially
distributed.

No need to buy a digging machine. Just lay some uniformly distributed,
shallow-buried wires, not necessarily all of the same length.

First try about 8 wires. If after trying out the system you feel
dissatisfied you can easily lay some more.

To answer one question "And what's so magic about 5/8 wave antennas? It's not even resonant,
> so obviously a matching network of some sort will be needed, but why
> 5/8? Why not 11/16? Or 3/4? Or something else?"

So why would anyone use a 5/8 wave antenna if they have to go through all that extra work? After all, a ground plane antenna provides a nicer match. There are a couple of answers. The first is GAIN. The computer shows that the antenna (mounted 1 foot above ground) has a gain of about 1.5 dBd higher than a dipole's gain (also mounted 1 foot above ground.)

The second reason you may want to use the 5/8 wave vertical is to obtain a lower angle of radiation. A half wave antenna's radiation peak angle is 20 degrees. You'll find that the 5/8 wave antenna's angle of radiation is just 16 degrees making it an even better dx antenna.

See URL: http://ac3l.com/five8th.htm

SOME MORE INFO
About Mobile Dual-Band 2m/440 -- Roger K6XQ advises - Can I build a 2m/440mhz 5/8 mobile antenna? A 1/4 wave on 144 MHz is 3/4 wave on 440. The SWR is usually acceptable on the 3rd harmonic, although that is partly due to the increased feeder losses on 440. But SWR is not the whole story. A 3/4 wave radiator on 440 has radiation lobes that send some of your signal at high angles, not toward the horizon where you probably want it. This is usually not so severe to make the antenna unusable, and may be considered a reasonable compromise for the dual band coverage. A 5/8 wave antenna on 144 MHz is 15/8 waves on 440. If you do the simple math you will see that on 440 you will have almost a 2 wavelength antenna, which is becoming what we call a "long wire" on the HF bands. As you probably know, a long wire radiates with multiple lobes, the largest of which are toward the ends of the wire. In other words, most of your signal will be radiated up toward the sky. The reason for the coil in commercial dual band antennas is to phase the antenna currents so you actually end up with two colinear elements which both radiate at low angles, reinforcing each other and providing gain. Without the phasing coil you get multiple undesirable lobes. Also keep in mind that 5/8 wave is NOT a resonant length. There are several ways to compensate for the reactance at the base of a 5/8 wave radiator, the easiest being to add a small inductance in series which makes the antenna electrically equivalent to a 3/4 wave. (3/4 wave is resonant, as you have already discovered). Given that the gain advantage of a 5/8 wave antenna over a 1/4 wave antenna is probably not noticeable except under the most difficult conditions, and even then may or may not make a difference, my suggestion is to stick with the 1/4 wave antenna. It is simple and works OK.

Above 5/8 wave the antenna exibits split lobes - so 5/8 is considered the
optimum

Yes it requires a matching network - but easy to implement

II use a quarter wave around my area as the repeaters are usually up on
mountain tops - thus a higher radiation works well.

On the open highways I use a 5/8 wave -- ranges way down the road.

Yep use a SWR meter and check resonance on the two bands -- now you will
have piece of mind

Wouldn't worry about how a dual band antenna is constructed - different
schemes can be used. Just so it is resonant as speced and adjusted if it can
be.

Anyone who has tried to operate multiple dipoles in parallel will know
that without heroic effort this is a false premise, nevertheless, the
practice continues.

Huh? Never had a problem here. But I don't "stack" mine like
some people do. That's what causes the coupling problems.
If you parallel feed two dipoles at right angles, there is very little
interaction at all. I spread mine apart as far as possible.
Problems are rare, and easily cured by just moving a wire
a few feet if it happens. It's the ones who tightly stack them with
short spreaders, that have the nightmare tuning problems.

Multiple radials of different length are
often operated in parallel because it is thought that there is then a
set that is optimum for each band.

Well, there is a set that is tuned for a certain band. They won't work
worth a hoot if they aren't resonant. But this applies only to
elevated
radials. On the ground, I agree...measuring is a waste of time.
Doesn't matter if the wire is insulated or not. Will act much the same
either way.
MK

Your making it tough on yourself. Lay the wires out on the grass. Get a bunch of coathangers that have multiplied in your closet and cut 6" pieces and bend into a "U" shape and use them to nail the wire to the ground.

Your lawnmower will never touch them and you save the rental cost of a trencher and clear out the coathangers. A real win win situation.
"Paul Hinman" <paul.hinman@shaw.ca> wrote in message
news:NFFQe.330061$5V4.212744@pd7tw3no...
I came across an interesting antenna the other day on the web. It called for four radials for each band that one would want to use it on. In order to protect the lawn mower I would like to bury the radials. If I use insulated wires for the radials can I bury multiple radials for different frequencies in the same trench. I would rent a small trencher like they use for underground power and utility feeds, make four trenches and drop in the radials, then cover them.

Thanx for any responses.

Richard,

Simply create a model of a coax feed to a poorly tuned dipole. It is quite easy to create a situation where a significant portion or the power is radiated from the coax feedline.

It is really quite simple: Coax is designed as an unbalanced transmission line from a source of a known impedance (nominally 50 Ohms for most common coax) to a similar known destination impedance. Under those circumstances there in trivial leakage.

However in the case where the 'antenna' at the other end is poorly matched it is possible to have significant radiation from the coax. Again look at a poorly tuned dipole.

The whole idea of coax is to use it the way it was intended. Then it works well.

Cecil,

To this point I do not know where the radiation comes from. I suspect it is from the antenna. The easiest case is to model a poorly balanced dipole directly feed by coax. It radiates significant power back down the shield.

After the response of the majority of posters to this concept I plan to find out more.

In the case where a mistuned dipole is being driven directly from coax there is radiation from the coax feed. This can only happen from current in the shield. Is this what you are referring to in the second paragraph?

Thanks,
Dan

I agree.

Transmission lines don`t radiate because they are mismatched.

Transmission lines radiate because they are unbalanced and this causes common-mode (unbalanced) current. In coax, the common-mode current flows on the outer surface of the shield and it radiates.

Best regards, Richard Harrison, KB5WZI

>Is this what you are referring to in the second paragraph?

Hi Dan,

Hmmm, The dipole is mistuned by the third conductor, the coax's
shield's exterior; otherwise, the dipole would be suitably matched
(this is the presumption, of course).

The source of the current on the coax's shield's exterior comes from
the excitation voltage seen across the dipole drive point (to which
the shield is common to one of the arms). The arm of the dipole that
is not attached to the shield, sees both its opposite arm, and the
undefined length of the shield's exterior path. This additional load
both unbalances, and mismatches. It is the unbalance that gives rise
to the Common Mode current, the mismatch simply comes for free.

Of course, you could fall into the condition where the dipole would
not normally be tuned, but through luck and happenstance, the addition
of the third radiator creates a match - this is strictly opportunistic
and sometimes the source for glowing reports of an otherwise horrible
antenna design. And this is the genesis of favorable accolades for
many of the mythic antennas that go by initials: CFA, EH, and so on
down the line. The "inventors" have simply contrived to tune the
driveline to their "inventions." Their aversion to discussing
driveline isolation is a hallmark of their "science." Their
insistence that choking the driveline is unnecessary or an impediment
to the design's utility, is further evidence of a generous thumb on
the scale of proof.

The addition of the choke gives its Z to snub this Common Mode
current. As both interior paths (that of the line's center wire, and
the interior of the shield) driving the dipole pass through the same
loops, their magnetic fields are unperturbed and see no additional
impedance. However, the "return" path of the shield exterior sees
these loops alone, and thus the Z is inserted into series with it.

If you think in terms of the W2DU style BalUn, the interior current/magnetic lines both transit THROUGH the beads, whereas the exterior shield current/magnetic lines CUT the beads - hence the choking action is more apparent in this configuration.

Actually, a perfectly balanced dipole can also radiate from the coax
shield because coax is unbalanced. Take a look at www.w2du.com and
www.eznec.com for information on baluns and chokes which tend to
reduce feedline radiation.

It appears to me that you may be confusing "balance" with "matching".
Those words have very different definitions.

A balanced 50 ohm antenna fed with coax and having an SWR of 1:1 is
matched but unbalanced and is likely to radiate from the feedline.

A balanced 50 ohm antenna fed with 600 ohm balanced line and having
an SWR of 12:1 is unmatched but balanced and is not likely to radiate
much from the feedline.

This has been my favorite way for a long time. The wires remain
removable and pretty much become hidden in the turf after a year. A
lot depends on the nature of the soil you are dealing with. North
Carolina red clay in August is especially tough. Six inches is longer
than I have needed. In the past I have ignored what might be optimum
and instead installed the radials I could. I am inclined to use
electric fence wire because it is cheap. Just use more of it. I
realize that this approach is not very academic, but I feel it yields
the best results in the long run for a given set of conditions.

My current location seems especially prone to lightning so I expect it
will be prudent to tie the radial system to the house ground with #6
copper wire.

A trencher is far overkill. Any sufficiently hard disk can cut through
the turf and inch or so. That is all that is needed for burying a
radial. I have about 30 radials for a Butternut Ground plane. I used
an old circular saw blade which I put on an improvised axle to cut
through the turf. I used whatever wire I had on hand at the time, some
bare, some insulated. It works fine. One thing to notice though is
that more radials will somewhat increase the bandwidth of the antenna,
but not anything which can't be overcome with a transmatch. The
radials do have to be radial from the antenna. If you crave super
efficiency though you may have to go to the extremes of Jerry Sevcik
(sp) who wrote a series of articles and books on vertical antennas in
the 70's. I have nearly 200 countries though with just the Butternut
and about 100 watts so you will get out.

Your reference to "getting a picture" implies that you are refering to
satellite television. Many of the dishes have off centre feeds set below the
apparent axis of the parabola. that means the incoming signal is at the
oppsite angle above.
Those dishes also have very narrow beamwidth making aiming VERY
precise.

The original poster is asking about an antenna for the Worldspace satellite
radio service. The antennas used for that application have very much wider
beamwidth.
In addition it's a different satellite in a different location.

Hope this clears the matter up a bit.

Not "Allah," but "El." The two names are clearly linguistically
related, but they are not the same.

> Yahweh, Jehovah, and Allah are all the same

Untrue. The claims of Christianity and Islam, their disciplines, and
their core beliefs are different. It's simple-minded reductivism to
claim that the Muslim Allah and the Christian God are the same. Muslim
and Christian beliefs cannot be harmonized without doing violence to one
side or the other. If one is true, then the other is false.

True enough, as far as it goes. But loving Muslims doesn't imply loving
everything that they do. Love isn't "being nice".

Yes, Elohim is a plural word. It doesn't necessarily signify that
Yahweh is one of many gods. Some grammarians have referred to it as a
"plural of majesty".

North American Indians call him ("God") "The Great Spirit", The Great
Spirit works for me, as will God, Yahweh, Jehovah, Jesus, "The Holy
Spirit", "The Father", etc...

Allah I would more liken to satan--"The Great Deceiver"--it which can
appear to some as "An Angel of Light." It is a yin-yang thing...
good-bad, light-dark, evil-good, etc...

I'm currently using a three-wire dipole with wire separation of about
4-5", wires cut for 40/20/10. It works quite well, with acceptable
SWR across each of those bands.

I'd expect the one in the ARRL handbook to have stronger coupling
between the wires, due to their close proximity, and thus more
interaction. Trimming it for proper operation might be trickier, and
it would not surprise me if the SWR bandwidth was narrower than would
be the case for a multiwire dipole with broader separation between
wires.

Well, this is a ham radio group and we don't "broadcast", we transmit
to at most a few individuals at a time.

"Exciters" are transmitters that are usually used to "excite" a
following amplifier. Because many (most) amateur power amplifiers of
the day require tens to maybe 100 Watts input to deliver rated output,
an exciter might well be a 100 W transmitter.

Like someone else said - instead of a trencher, why not try a edger.
You can buy an electric edger and a long extension cord cheap enough - probably cheaper than renting a trencher.
I heard one person say he just purchared a new chain for his chainsaw - and used the old chain to make the trenches for radials.
Another thought - don't do radials at all - hire a front-end-loader to bury a few chain-link fence sections and tie ground to them.

Be sure to grunt like the tool-man when installing the radial system - its a tradition.

In Arabic, (and I was a professional government Arabic linguist and Middle East specialist) "Allah" means "THE God". The "AL" in Allah is the definite article in Arabic and in the Arabic script, the definite article gets physically linked to the word it defines. The word "god" (lower case) (in Arabic is Lam, Lam, Tah Marbutah or LLH. Unfortunately I can't do Arabic script on my home computer. Also Arabic script does not have capital letters.) That word is transliterated LLH. (That "H" is really a glottal stop like the second "h" in "huh." There are several Arabic letters which can be transliterated "H" in Roman script. The Tah Marbutah, it looks like an "o" with two dots above it, has no real equivalent in Roman script, but is pronounced as a glottal stop. Like Hebrew, most vowels are not written out in Arabic except in linguistic texts and the Koran...they are simply diacrital marks. "LLH", without the definite article, was used to described dieties in Arabic long before Muhammad and the Koran came around in ca. 632 AD when the pre-Islamic Arabs were mainly animists.

From an Islamic perspective, "Allah" is the same God as the God of Jews and the Christians. The Koran makes that quite clear. (The Koran also argues that the Jews didn't go far enough in their beliefs and the Christians got it wrong, but further argues that an Islamic believer is unlikely to convert them and they should be left alone and respected as "People of the Book.", the book in this case being the Pentateuch.) Whether you wish to accept that concept, of course, is a theological question. Most academic comparative theologists, even those at Christian and Jewish seminaries who are among the believing, do accept that premise (that the God is the same entity) even if they don't believe in the premise that God made the Koran his last word on the subject. The Islamic formula, as written in Arabic, states that there is no god (indefinite article) (llh) but THE God (Allah) with the definite article. The word has its roots in the proto-Semitic common to Arabic, Aramaic, and Hebrew. Again, from an Islamic perspective, Abraham, Jesus and Mohammad prayed to the same God, but certainly the vocabulary was different.

Your theologic milage may vary, but here is at least is a linguistic and historical basis generally accepted in academic circles.

Jon W3JT (Retired Gov't Linguist with Masters in Middle East Area Studies.)

4830. Diamond W-8010 or general advise on shortened dipoles with traps or coils

Make sure your antenna can handle 600 watts, and presents a near 50
ohm resistive match. The 4 MRF150 fets do not like mismatches on their
output. They are $125 each, and can fail, even tho they have VSWR
protection in the Amp. If you don't abuse the Amp it will do well.
I have never owned one, but homebrewed an Amp that was identical.
Since this is an antenna group, let us know what you intend to use.

I am truly disappointed with the long-running discourse on balanced and unbalanced feedlines and the power radiated therefrom. It's been going on for years.

Nobody, especially poor novices, has ever learned anything from it.

99% of it is bafflegab.

Few of us understand what on Earth is being waffled about. And those who do, prefer not to waste their time by joining in.

The reason I'm making this seemingly outrageous statement is that NOBODY HAS EVER QUANTIFIED, not even once, what they are waffling about. This demonstrates a great ignorance of the subject.

(Remember what Lord Kelvin said about the ability to measure and quantify what it is you are gabbing about and how that ability is directly related to what you really know about it.)

Perhaps somebody might be prepared to state the power actually radiated from feedlines in watts. At least it may create the impression you know what you are talking about.

It might possibly be at such a low level that, in the great majority of cases, it's not worth all the megabytes of bandwidth which are wasted on it.

As an unbiased World Citizen, I now find myself half-way down a bottle of Merlo, 2000, a produce of France. But I have in reserve some decent Californian stuff.

May I say how saddened I am to learn about the terrible disastrous storm which has befallen some of the Southern states.

In a way they are the same. Exciters are usually thought of as a low power stage that drives a larger amplifier. The exciter plus the amplifier stages are what I would call a tansmitter. Many of the vhf/uhf comercial transceivers had a low power (around 100 to 300 milliwatts) exciter to drive the amplifier section that would take it to 25 to 150 watts out.

The last time you made a similar statement (not long ago) I referred you to my article on baluns, then and now available at my web site, which includes measurements of imbalance when various balun configurations are used. Have you looked at it yet?

> Perhaps somebody might be prepared to state the power actually

Let's begin a little more simply. Can you tell us how many watts each portion of an inverted-L antenna radiates? How about each element of a Yagi? Or even, say, the outer 1/3 of a dipole?

If you can't, may we assume that you don't know what you're talking about when you discuss antennas?

Suppose I have an antenna some distance from the house. I run the transmission line down from the antenna, bury the line, run it underground to the house, place a lightning arrestor and ground just outside the house, then run the transmission line up the side of the house to the operating position on the second floor. Does anyone see a problem with this arrangement? I can't imagine that a lightning would "want" to travel back up toward the operating position when it has a good ground (at the arrestor) closer to the antenna.

There are sooo many digits to the left of the decimal in lightning
that ALL bets are off if it strikes the antenna. The arrestor will
ground induced voltages from nearby strikes and wind ot precip static.
Ground your antenna when not in use by diconnecting the feedline and
grounding both sides. Don't operate when mother nature is
transmitting.

> That should have been more radials DECREASE the bandwidth.
> Sorry,
>
==========

It may be considered by some that a decrease in bandwidth is a
disadvantage. What really matters is that more radials result in an
improvement in power radiating EFFICIENCY.

Albeit with a diminishing rate of return.

In ordinary garden soil, first lay about 3 or 4 shallow buried radials
and test the results using the receiver S-meter.

Then increase the number of radials by 50 percent and look for an
improvent. If there is no measurable improvement then, to be certain,
increase the number of radials by another 50 percent.

Keep increasing number of radials until there is no improvement and
then do a final increase of 20 or 30 percent. Even with very poor
garden soil, in all probability you will not exceed 20 or 30 radials.

Just ignore the ridiculous instructions in the handbooks and
magazines, and from old-wives, to lay the magic number of 120 radials
at the outset.

Due to reciprocity, any improvement on receive, as indicated by your
S-meter, will be exactly followed by the same improvement on transmit.

I've had mine for about 5 years and love it.

I highly recommend getting an LDG AT-1000 auto antenna tuner for it. Makes a really slick combination and pretty much assures a flat load for the amp to see. (Assuming you don't need 160m as the LDG doesn't do 160).

I tried some real torture tests on the LDG and it has been amazing...like feeding a 40m inverted V on 80m....terrible idea and a rotten antenna...but the LDG matched it right up. Very few auto-tuners can pass that particular test.

The ALS-600 has excellent protection circuits. I have tested them on several occasions when not paying attention. The load fault circuitry works very well.

I have no reservation about recommending the ALS-600. I use it on both SSB and CW, even RTTY at reduced power. I have used a TS-870s, FT-847 and TS-2000 to drive it and had no problems. IMD measurements on PSK31 indicate -30 dB with the ALS-600 running 200w output, driven by the TS-2000.

Have fun. 73

Depends. I have had 30 - 45 minute QSOs with EU stations while running barefoot on 75. On the other hand, when I check into a local net, I run the amp at 1/2 power, about 600W. There is one person on the net who does not run an amp. Some weeks I only copy him 10 - 50 %. Others have the same experience. These people are all within about 50 miles from me.

QST tested the Ameritron SS amp, and liked it. They also like the switching power supply, which costs extra. I believe the linear supply is choke input, unregulated. These are 48V supplies.

There is one additional step which seems, from many anecdotal references, to provide further help. Somewhere along the
cable route, run the coax through at least two sections of steel electrical conduit. Size immaterial, and grounding
optional. And they need not be connected together. Theories about why this works run from it forms a lossy coax for
the lightning induced wave on the outside, to impedance mismatch on the outside to eddy current losses in the steel.
Whatever the mechanism, I know of several locations where it seems to have reduced the damage from continuing lightning
strikes. And it is certainly cheap enough to include.

Broadcast stations are licensed at various power levels, and indeed, AM stations typically (except clear channel) change
power at sunrise and sunset. FM stations are also licensed at various powers, where the antenna height above average
terrain and antenna gain also enter into the radiated power equation. So manufacturers design an exciter which provides
a set of features desired by some large segment of their target customers, and with that a series of amplifies of
different power levels to meet the license parameters.

All,

Below is a link to a site that claims to model coax radiation from a dipole.

http://www.smeter.net/feeding/feedpowr.php

I have compared several of the models from this site with other models and they are close.

I have tried several parameters and have gotten results from a very low level with a close match to over 90% of power radiated in the feedline when the dipole resonance is far from the transmit frequency.

We may use this model for a couple of things. It is available and it predicts radiation. That gives the opportunity to create a test. I for one are willing to experiment.

Source record: 71319

PLEASE, I need help.
If anyone can run the numbers,
I have tried Quick Yagi with little success.
I have a pair of the OLDER Hy-Gain 2m antenna's. There design was a
200ohm (I think) Hairpin match (to 50ohm) with the reflector and
directors INSULATED from the boom.
Current model for the last 10+ years is the elements are not insulated
from the boom.
I want to respace the elements, possilbing cutting down as it is
easier than lenghting them, to get the best
1. Beamwith/pattern
2. FB
3. Gain.

I am only going to use them on 2M SSB with a center freq of 144.250

Here are the measurments.
14' boom
El Lgth Space
D6 34.62500 32.25
D5 35.00000 26.75
D4 35.12500 25.75
D3 35.12500 28.25
D2 35.25000 22.25
D1 35.50000 12.75
Driven 32.75000 16.75
Ref 44.37500 1.75

Notes. Measured in Inches. Reflector is mounted 1.75 inch from end of
boom, D6 is 1.5 inch from end of boom. All Elements are INSULATED on
top of the boom. If needbe I can remove 1 director as the insulator
need replacing.

Most folks use 100 watts or less so you can talk to most people with the same power level or less.
Antennas have the ability of amplifying the receiving station's signal to you as well as your signal to them. (gain)
building and designing Antennas is a way to learn and and enjoy the hobby.
contrary to what some may say, you don't have to be an engineer to enjoy the hobby.
If you need the amplifier (like on 80 meters at 9 pm when everyone is trying to claim a freq for an impromptu net) - then its usually less stressful to just switch it off until the band is less busy.

4857. Dual Band "on glass" antennas, good or bad?

What do youse guise think of on glass dualband 2/440 antennas? I have never used one but are now considering it as an option rather than drilling a hole in the roof of my new Chev Silverado. An on glass antenna would also be much easier to route the coax with rather than needing to remove the headliner. Anyone out there that was impressed or particularly dissappointed by on glass antenna performance? Any issues with mounting on a window that has the defog element in it? Thanks, Mike K7MH.

Used a Larsen 2 meter glass mount and was happy with the performance,
no experience with a dual band though. As to mounting it on the defog
element - bad idea.

Assuming your "ground" system outside the house is fairly substantial,
(not just a single rod), then I'd say your system is about as good as it
would get.....

However, with a direct strike, there is NO guaranty! Even a tiny
fraction of a gazillion volts can cause you grief. Best bet, disconnect
the coax in a storm, too!.

Roger, ZR3RC wrote:
"These dishes also have very narrow beamwidth making their aiming very precise."

You are right. Even an 18-invh dish needs a pretty good elevation angle in the UK to get best reception in the KU band from a satellite parked over the equator. I checked the Direct TV website. A geostationary synchronous bird flys at more than 22 000 miles above the earth`s surface. The horizontal distance is always a fraction of the altitude of the satellite, so the elevation angle for line of sight is substantial no matter what the azimuth. I am still puzzled as to why so many dishes I saw in Scotland were aimed so low.

Direct TV gives instructions on how to align a dish in their service. They send an initial elevation angle "tick-mark" setting to the customer. It is then up to him to acquire the bird and optimize setting the dish for best signal.

Direct TV has 3 satellites available to the customer, and though they are several degrees apart along the equator, one azimuth setting of the dish is expected to give satisfactory signals from all three.

Best regards, Richard Harrison, KB5WZI

Richard

This a L band receiver. Their satelites for the ASR WS 201 pump out alot
of power with traveling wave tube amplifiers at about 1,400 MHz..
The OP may be on the far edge of the coverage "footprint" from the
satellite over Africa so his antenna positioning could be more critical that
locations closer to Central Africa.

How many $per watt for the Ameritron 600? Ameritron lists the ALS-600 at
$1299. For base station usage you need the power supply. Total package
list price of $1428. Or, $2.38 per watt [SSB]. [600 watt]

The AL-811H lists for $799 or $1.00 per watt [SSB]. [800 watt]

The AL-80B lists for $1349 or $1.39 per watt [SSB]. [1000 watt]

The AL-1500 lists for $3045 or $2.03 per watt [SSB]. [1500 watt]

If you are considering base usage the AL-811H is less than 1/2 S unit
below the AL-1500 at about 1/2 the price.

The ALS-600 is only 1 1/4 S units above a 100 watt base or mobile station.

I own the AL-80B. It has about 1/4 S unit below the AL-1500. [SSB]

Save some money and put it to good use on your antenna system.

You have to design for one of teh above 3 items. It is not usaully possiable to have the best of all 3. In most areas there is not enough activity to worry about the RB or pattern. Just go for the gain.

90% of all lightning strikes can be described as less than 100,000 amperes peak, multi strike, 600 amperes continuing current at a critical E field
strength of more than 12,000 volts per meter pre strike. [USAF standard lightning
model].

A lightning arrestor uses a spark gap, AKA plasma, to protect the downstream equipment. The spark gap can be modeled as a non-linear zener diode with a higher ignition voltage than sustaining voltage. In other words the voltage needed to fire an arrested is great than the voltage after it fires.

The large currents set up magnetic fields in the local area that induce voltages INSIDE shielded enclosures [eg cables]. The current flowing on the outside of your coax induces voltages on the inner conductor [via transfer impedance, Vance et al, IEEE Transactions].

Conclusion: there are at least three possible sources of trouble from a lightning strike on or near your antenna: 1) transient from the lightning arrestor 2) induced, -L*di/dt, voltages inside intentional and unintentional loops, and, 3) transfer impedance induced voltages on center conductors of coax cables.

Solution: Ground everything you can using single ground point principles [just as you described], disconnect AND THROW antenna cables OUTSIDE of your house, unplug all equipment from power mains, buy good insurance, buy more insurance. [I just replaced my IC-756 Pro II with good insurance coverage][My IC-746 co-located 6 inches from the IC-756 Pro II did not fail from the same lightning strike][50+ years in ham radio and this is my first loss to lightning]

I live near Boston. We have a professional baseball team and the team has a 'unique personality' named Manny. There is a statement that 'Manny does what Manny does!'. Paraphrasing this saying for lightning: 'Lightnign does what lightning does!'

Please note that the third wire to ground creates the unbalance
that causes feedline radiation. You seem to be confusing cause
and effect. The cause of the feedline radiation is the existence
of that third wire, not SWR. All it proves is that feedline
radiation is caused by that third wire path which unbalances
the source currents.

Hi All.
I've still not found the way to seperate the outer caseing from the inner radiating wire, even looking at the web sites photo's and destructions. Originally I thought I'd found the answer, because there was a small blob of solder on the chromed metal collar that I thought terminated the wire, unfortunatly not so. I have removed all the fixing glue from around the collars and expected to be able to remove/seperate it but with no luck. Any of you guys got any pointers before I end up destroying what might be a potential good 10 Mtr antenna. Any body done this project and been successful? The web shots are reasonable to deduce what to do, but attaining it is very different. TIA Dave.

If it is true it proves that a driving a "bad" load can cause the coax feedline to radiate a significant portion of the feed energy. At this point I am not sure what word to use other then 'bad', but I due intend to perform experiments to measure and verify what is happening and the model.

Amateur Radio Volunteers Involved in Katrina Recovery
NEWINGTON, CT, Aug 30, 2005--Amateur Radio Emergency Service (ARES) volunteers in Louisiana are engaged in the Hurricane Katrina recovery effort, and more are waiting in the wings to help as soon as they can enter storm-ravaged zones. Winds and flooding from the huge storm wreaked havoc in Louisiana, Mississippi and Alabama after Katrina came ashore early Monday, August 29. Louisiana ARES Section Emergency Coordinator Gary Stratton, K5GLS, told ARRL that some 250 ARES members have been working with the Red Cross and the state's Office of Homeland Security Emergency Preparedness. Much of the affected areas remain flooded and dangerous, however. As a result, state officials have not allowed emergency or other units to enter the flooded zones, and there is still no communication with many coastal areas.

The West Gulf ARES Emergency Net remains active (7.285 MHz days/3.873 MHz nights), and radio amateurs not involved in emergency communication have been asked to keep these frequencies clear when the net is in session.

A high volume of health-and-welfare requests reportedly is slowing the passage of critical tactical and emergency traffic. The Salvation Army Team Emergency Radio Network (SATERN) on 14.265 MHz has been accepting and handling health-and-welfare inquiries on the air and via its Web site.

Will you please describe the details of your experiment where you
claim 90% of the power is radiated from the feedline? How did you make
this measurement?

How do you figure? That isn't in line with anything found elsewhere in
the Bible, or any respectable hermeneutic.

Does the Queen of England mean to imply that there is more than one of
her when she uses the "royal We"?

Reg, G4FGQ wrote:
"Perhaps somebody might be prepared to state the power actually radiated from feedlines in watts."

Someone has. A feedline is a way to get energy from here to there. Usually we want to keep all the energy on or close to the line as it travels and lose as little as possible to radiation and conversion to heat.

Terman gives an approximate formula credited to Sterba and Feldman for radiation from a 2-wire nonresonant line, provided that the lengrh is at least 20X the spacing and the spacing is less than 0.1 wavelength:

Radiated power/Isquared=160(pi D/lambda)squared.

D/lambda is the spacing in wavelengths

I is the rms line current.

Terman notes that the parallel line radiates 4X the power that a doublet of length equal to the line spacing would, providing that the line and doublet currents are equal.

Terman provides a figure to be used to adjust the estimated radiation upwards for longer feedlines (up to 5 wavelengths), and for greater heights (up to 0.5 wavelength above the earth).

See 1943 "Radio Engineers` Handbook", page 194.

Here is the latest info that I have:

Fred W4JLE DEC SEOC SC

The on-the-ground situation in SE Louisiana and SW Mississippi is as bad as television is reporting. Neither state is permitting disaster relief agencies into the affected areas except on a very limited basis and only then where conditions are stable. Nearly everyone is still staging as close by as possible and waiting.

The Louisiana SM (Mickey Cox K5MC) and SEC (Gary Stratton K5GLS) are in communications with state officials, who have directed them to NOT advertise for volunteers. Some volunteers have been requested, and these are being staged at the state EOC.

The situation for the Mississippi SM and SEC, Malcolm Keown W5XX, in Vicksburg MS is very uncertain. His station is completely on the ground and EchoLink repeaters in the area are off-the-air. Attempts to contact Assistant SMs have been unsuccessful.

An AB2M.net Amateur Radio operator registration web site has been setup and is ready to go public when approval is received. Some Amateur Radio operators are known to be traveling towards the affected areas with emergency services and disaster relief agencies as dedicated communications resources.

Despite everyone's nearly overwhelming desire to help, about all we can do right now is to make preparations for a prompt response when the officials finally give their approval. None of us know when that will occur.

The West Gulf ARES Emergency Net remains active (7.285 MHz days/3.873 MHz nights), and radio amateurs not involved in emergency communication have been asked to keep these frequencies clear when the net is in session. (this is an emergency H&W freq)

A high volume of health-and-welfare requests reportedly is slowing the passage of critical tactical and emergency traffic. The Salvation Army Team Emergency Radio Network (SATERN) on 14.265 MHz has been accepting and handling general health-and-welfare inquiries on the air and via its Web site.

COMPANY OR ORGANIZATION INFORMATION:

Bozak Antenna
8 Timberwick Drive
Clifton Park, NY United States 12065
(518)373-8069
www.bozak.org

COMPLAINT INFORMATION:

Complaint #: 414840
Complaint Type: Company (other than automobile)
Date Received: 9/12/2001
Primary Complaint Classification: Credit or Billing Disputes
Secondary Complaint Classification: Delivery Issues
Complaint:

To whom it may concern:

Mr. Steve G. Bozak was contacted in mid July 2001 regarding products (eg. antennas and coax cables) which were available for sale from his firm. Mr. Bozak quoted prices and then later changed the quote to reflect higher prices (25% higher) without my authorization. Mr. Bozak concludes that since I gave my credit card info that I agreed in principle with the altered price quote (which I did not agree too).

In addition to the order being 2-3 weeks late (because his firm did not have enough coax cable on hand), I then had to follow-up and specifically request a copy of the original billing invoice. When the invoice was finally received in late August, and after noting the higher prices charged, I immediately called and complain to Greg (Bozak's sales rep). Greg was informed that I received a lower price quote in mid July. Greg requested that I forward that quote which I did. After reviewing, Mr. Bozak wrote back on September 12, 2001 that "I am sorry for the confusion about the prices.... every effort has been made so this does not happen."

Thus, Mr. Bozak concedes that he (and his organization) screwed up but they want me to eat the higher costs. This is why this matter is being forwarded to your offices for recording and resolution purposes. Prospective customers need to know about Bozak's deplorable customer service/business practices.

Since he lives about 190 miles NNE of NO my guess is that not only is the TOWER OF UNION MS down, but he lost the trees that were attempting to hold the TOU up. He is most likely out of electricity and telephone (internet connection) lines.

If he suffered any damages I do hope for his recovery.

Dan wrote:
"We may use this model for a couple of things."

Dan attached a posting from Reg, G4FGQ.

Reg`s description of the "Centre-Fed Dipole - Radiation from Coaxial Feedline" tells it as it is.

About 45 years ago, I (Richard Harrison) worked for a company exploring for oil in the Chaco Jungle of Bolivia. Communications were by HF radio at all sites in the jungle and at offices in Cochabamba and La Paz. Radios were Collins 30K-5 transmitters and 51-J receivers at all locations. All antennas were center-fed 1/2-wave dipoles up only about 1/4-wave due to economics and generally were broadside to some favored direction. The feedline was also about 1/4-wavelength for convenience, but the antennas loaded, took a lot of power and the 30-K finals dipped OK. Soil at the radio sites was mostly sand and didn`t really ground anything very much. The length of the coax presented a high impedance to the outside shield of the coax cable at the dipole, whatever it might have been.

At 1/4-wave antenna height, directionality was small and whatever the coax radiated, it likely filled-in any nulls.

All stations could clearly hear all others all day, so the operators were satisfied. Much of the radiation was straight up so we likely bebefitted from near vertical incidence propagation. The transmitters shook the aether with their power, but the 51-J has a nice dial but not much else. Nevertheless, everything worked.

My previous employer had given away all its 51-J`s, they were so sorry, and replaced them with Hammarland SP-600`s. I didn`t take a 51-J, I was using one of the Super Pro`s.
My experience is anecdotal.

Best regards, Richard Harrison, KB5WZI

The storm was quite strong even in central MS, probably still category 1
there. Many even "built-by-the-book" towers would be destroyed from there
south, especially if trees fell across the guy wires.

Here in northeast MS (Starkville) Katrina was at strong tropical
storm strength. Several trees in my yard were blown over. Fortunately
my two towers (100',70') survived and the only damage was some
bent/broken 15m yagi elements from flying tree branches.

Cecil

How wrong would it be to say that the *coax* part of the line doesnt
radiate at all?
I see this as a situation where the *outer shield* of a transmission line
is conducting current that radiates.
It seems that a "balanced" antenna that is comprised of a single
conductor and a L shaped conductor that includes the outer conductor of the
coax, could be fed with a balanced line for modeling.

Jerry

The calculations you quote assume equal and opposite (i.e., purely differential mode) currents in the feedline conductors. The topic under discussion is radiation due to common mode current.

Hello all,

I was just doing some more reading and came up with a few more questions. It seems that I failed to take into account adding a harmonic filter between my antenna and RF amp. However, in regards to low power transmission (100W), would I still need harmonic filters?

I saw a design for a 1kW AM system and it had several huge harmonic filters. I think the total weight was about 60 lbs. I want to keep my system as small as possible.

Is there an alternative setup to get rid of the harmonic filters?

Thanks!

use a decent radio and you shouldn't need extra filters.

My old Cushcraft A3 is more than likely due for a take down and refurbish. Ive not really touched it in a long time and have never opened the traps. 15m is suffering so I may have a bad trap.

So, I did a net search and not too many have posted how its done. SOOOO, with that I come hat in hand for hints/tips etc from those that have went there.

It's a radio system use for missionary work in third world countries.
We are not too worried about breaking FCC rules since we will be using
them outside the US. My concern with the harmonic frequencies is mainly
protecting the transmission system and also not interfere with other
sister stations. From what I've read so far, some harmonic frequencies
might couple to the transmitter input and that can affect the output.

I guess what I really don't know about is how exactly harmonics affect
the system... and if a DSP based transmitter would also need these
bulky harmonics filter.

Hmm..also, wouldn't the harmonic filters normally be part of an antenna
tuning unit?

Why are you wanting to take it apart ? Its unclear what you want to do.
I believe its a sealed unit - and I know it makes a good 10-meter vertical.
Hook it up and try it - if it works, then use it - if not then get a new one
or use a wire antenna.
Its just an end-fed half wave. But the antenna as a package is light-weight,
easy to adjust (with the rings), and easy to deploy. That makes it popular -
but the hype about a lot of gain is just that - hype.

What I was taught is that in a properly installed antenna system the
coax will not radiate. If the antenna is not properly matched to the
coax you get current flow along the outside of the coax shield.

Thanks for the reply, all!

I was calling some companies just to ask around. It seems like when it comes to AM exciters I would still need to hook it up to an AM transmitter. However, for FM exciters, I can directly hook them up to a power amp.

The usual mechanism is when the 2nd harmonic of an active transmitter (F1) mixes with the fundamental of a nearby station on F2 to produce an IM product at 2*F1-F2. This can occur in a nonlinear output stage of F1, and harmonic filters normally have no affect on the in-band IM product that is generated.

The control is to filter the external fundamental signals from entering F1's output stage via the antenna connection, so they are not present there to generate spurs.

> Hmm..also, wouldn't the harmonic filters normally be
> part of an antenna tuning unit?

It is more closely connected with the harmonic "signature" of a given tx, and so is usually supplied as part of the tx system. The tx OEM has to certify that his tx meets specs for harmonics and spurs, and couldn't do that unless the performance of the filtering network was under his control.

> If it is true it proves that a driving a "bad" load can cause the coax
> feedline to radiate a significant portion of the feed energy.

You need to define "bad load". A "bad load" for unbalanced line
is a balanced load, no matter what the impedance. A "bad load"
for balanced line is an unbalanced load, no matter what the
impedance.

The third wire used in the aforementioned software is designed
to unbalance the system, no matter what the impedance.

To illustrate a balanced system, a fourth wire needs to be
added in parallel with and about four inches away from the
third wire. Then compare the currents in the third and fourth
wires under conditions of changing loads.

The physical construction of the coax (ideal version) ensures
that the inside of the coax doesn't radiate because, for
ideal coax, the internal currents are perfectly balanced.
Any unbalance in the currents is forced to the outside shield
by the laws of physics.

The winds I'm sure were stronger than that.

Note the station stopped recording (broken?) at 1pm. They probably saw
much higher wind speeds. Even up at Tupelo (substitute KTUP in above URL)
there was a gust of 53 mph recorded. Also try Birmingham BHM, which is
quite a ways to the east.

Is "matched" the correct word to use there? A 50 ohm balanced dipole
is perfectly "matched" to 50 ohm coax but the feedline will likely
radiate. A 50 ohm balanced dipole is not "matched" to 600 ohm balanced
line but with proper attention to details the feedline will like not
radiate much.

> Someone wrote "You don't need a linear unless you're on 80 meters - then
> you really need a
> biggie"

Agree and disagree

For example, let's start with a 100-Watt exciter then add an afterburner of 800 Watts. Doubling power is 3 dB and an S-unit is 6dB. So from 100W to 200W is 3dB, 200W to 400W is 3 more dB, and 400W to 800W is 3 more dB for a total of 9 dB or only 1-1/2 S-Units possible increase on the receiving end. One can achieve almost the same result with a 3-element beam.

BUT Although one and a half S-Units does give a little more oomph while working a pileup, it really comes into play for weak signal work where if it gets you just up out of the noise on the receiving end, two way QSO's may be possible where without the linear, the DX just can't copy. I can attest to this many times on any band.

On the other hand I have worked DXCC - QRP - 5 Watts

A lot depends on propagation (of course)

Dave

I'd agree with your statement if "matched" doesnt refer to *impedance*
match.

Cecil

I failed to emphisze that any current on the outside of a coaxial
transmission line are out of the bounds of the defination of Coax.

I've always been puzzled why people thought that how things end up was a surprise. If you took someone who somehow was not aware of the history and said to them: You've got two societies of people on the same land: One group does not believe in private property ownership, and the other one does - which one do you think over time will end up taking posession of and claiming - how else can you put it? - *ownership* of that land? I'm not saying it's right, or that how it was done was right, but I often question the honesty and intelligence of people that act appalled at how it ended up. I mean - it should be a required question on any intelligence test, and anyone who anwered that the group that didn't believe in private property ownership would end up displacing the group that did should be put in the moron category regardless of how they answered any other questions.

Not many can put up a 3 element beam for 80 meters, 40 meters either. Even
a rotatable dipole is not an option for most on 80. The amplifier will sit
on the same desk as the rig in most cases.
Granted it will not do anything for my receive.

I don't use my amp very much. It did come in handy as I was talking to a
portable station last Sunday morning on 80 meters. He had a bunch of static
and qrm (Shelby hamfest was where he was at) and by me running an amp I
could get over the local noise he had.

7.78 Db BETTER [+1 1/4 S unit] than 100 watts.

Upgrade the vertical to a beam and the net gain can be as high as +19.78
dB [3+ S units] on the path:
1] + 6 dB in receive
2] + 6 dB in transmit
3] + 7.78 dB for the amplifier.

For $1400, a beam has a much better return on investment than an
amplifier by itself.

The #1 rule I teach new or aspiring hams is "Your station efficiency,
and your enjoyment, is directly proportional to your antenna."

It's too bad people are being taught this. As a number of others have correctly said, impedance match has nothing to do with whether or not a coax (or symmetrical twinlead line) radiates. Radiation is due to other, unrelated causes.

Just don't make the common mistake of thinking that the units on your receiver's S meter are 6 dB. That can lead to some extremely mistaken conclusions.

Hams keep insisting that an "S-unit" is 6 dB, while the marks on typical S-meters almost never are, and sometimes are much different (< 2 dB for example).

A balanced antenna fed with balanced line, and the line goes away from the antenna perpendicular [90 degrees angle] for a minimum of 1/4 wavelength is a properly installed antenna system: [line has minimum or no radiation]

A balanced antenna fed with balanced line, and the line goes away from the antenna non-perpendicular [other than 90 degrees angle] for a minimum of 1/4 wavelength is an improperly installed antenna system: [line will radiate]

A balanced antenna fed with un-balanced line, and the line goes away from the antenna perpendicular [90 degrees angle] for a minimum of 1/4 wavelength is an improperly installed antenna system: [line will radiate]

A balanced antenna fed with un-balanced line, and the line goes away from the antenna non-perpendicular [other than 90 degrees angle] for a minimum of 1/4 wavelength is an improperly installed antenna system: [line will radiate]

A balanced antenna fed with un-balanced line and a properly installed balun, and the line goes away from the antenna perpendicular [90 degrees angle] for a minimum of 1/4 wavelength is a properly installed antenna system: [line has minimum or no radiation].

An un-balanced antenna fed with balanced line is an improperly installed antenna and the line will radiate.

NEED I CONTINUE??

I've been hearing calls for help from people stuck in attics
being routed through HF. Also , the usual H&W... So far,
the local people that have tried to go over there, and been
told, *Stay Away*!!!. They have plenty of local people from other
parts of the state, and New Orleans can't support any help
that does arrive. They have no way to keep them, feed them,
etc...So until they are ready, they are telling most to hang back.
I've been getting a good signal on WWL 870 in the daytime
using my big indoor loop.
Lotsa caller in, and things fairly normal on the air, cept, they
say they are running out of power, and no A/C, etc in the studios.
They are using all available power just for the transmitters.
Only station in town that is still going so far.
MK

I've been getting a good signal on WWL 870 in the daytime
using my big indoor loop. ....

Dang, I just checked it now, and it *seems* to be off the air...
Hope it's just propagation.... Hope they didn't finally lose
power... It is 6.30 PM, so it's possible I just lost them due
to the propagation...I get them much better in the day, than
night. I hear a station on freq, but don't know if it's them or not.

Here's another posting referring to 6 dB "S-units". Have you actually measured how many dB between marks on your receiver's S meter? I have. Here's what they are, on my Icom IC-730, 40 meters, preamp off:

S1-S2: 1.4 dB
S2-S3: 1.3 dB
S3-S4: 1.6 dB
S4-S5: 2.3 dB
S5-S6: 1.8 dB
S6-S7: 3.2 dB
S7-S8: 3.1 dB
S8-S9: 4.0 dB
S9 - S9+10 dB: 5.6 dB
S9+10 - S9+20: 7.3 dB
S9+20 - S9+30: 6.6 dB
S9+30 - S9+40: 10.5 dB
S9+40 - S9+50: 11.3 dB
S9+50 - S9+60: 13.5 dB

So if I put up an antenna with 7 dB gain over a dipole (about par for a 3 element Yagi), it would kick my S meter from S2 to S6 when switching from the dipole to the Yagi. If I assumed my "S units" were 6 dB, I'd conclude my antenna had 24 dB gain. I'd be mistaken by a factor of 50 -- that is, I'd think my antenna had the gain of an array of about 50 Yagis.

I don't understand why we need a 6 dB unit which doesn't bear any fixed relationship to the marks on an S meter. Why not just use dB? Most hams can't measure 6 dB "S units" any better than they can measure dB.

I've got it. When somebody asks for a signal comparison and it's a 7 dB difference, I'll just tell him "My S meter went from S2 to S6, which is a difference of 1.2 S units." Everyone should understand that, right?

i wonder if anyone did any actual research on adding some pipe
sections?? wonder if that would woork?

i'd also recomend some good lightning surperssors such as those made
by ice they seem about the best

4929. There are 3 coaxial conductors.

Newsgroup: rec.radio.amateur.antenna
Date: 2005-08-31 23:59:51 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <df5g9m$l41$1@nwrdmz01.dmz.ncs.ea.ibs-infra.bt.com>
Source record: 71191

Dear all,

For coaxial cable, at HF, where skin depth is less than the physical outer conductor thickness, there are 3 conductors.

Conductor (1) = Outer surface of inner conductor.

Conductor (2) = Inside surface of outer conductor.

Conductor (3) = Outer surface of outer conductor.

The return path for (3) is the remainder of the universe. It behaves as a single conductor transmission line which has calculable Zo and attenuation. (To keep Lord Kelvin happy). When current flows on it, it also has a radiation resistance.

The currents in (1) and (2) are always equal and opposite in direction to each other. They are mutually coupled to each other by line inductance and capacitance.

The current on (3) is always independent of what flows in (1) and (2) because no mutual coupling exists between them. However, external coupling can occur and be deliberately or accidently induced at the ends of the cable.

Any current which finds its way on to (3), which ought to flow in the antenna, will result in the coax participating in the radiation pattern of the whole antenna structure.

BUT IT IS A SILLY QUESTION TO ASK HOW MANY WATTS ARE RADIATED FROM THE FEEDLINE.

OR, CONVERSELY, HOW MANY MICROWATTS ARE PICKED UP BY THE FEEDLINE ON RECEIVE.

The feedline cannot be treated in isolation as if it behaves independently of the antenna. For starters, the radiation resistances of the feedline and antenna do not add arithmetically. They interact with each other.

In summary, in your own language, the watts radiated from the coaxial feedline to a resonant 1/2-wave dipole, without a choke balun, can be forgotten about. There may even be a small advantage. Nothing is wasted where there are pigs.

Reg, G4FGQ
